

SOFTWARE TESTING

UNIT I

Introduction: Purpose of Testing, Dichotomies, Model for Testing, Consequences of Bugs, Taxonomy of Bugs.

Flow graphs and Path testing: Basics Concepts of Path Testing, Predicates, Path Predicates and Achievable Paths, Path Sensitizing, Path Instrumentation, Application of Path Testing.

PURPOSE OF TESTING

- ☞ Testing consumes at least half of the time and work required to produce a functional program.
- ☞ MYTH: Good programmers write code without bugs. (Its wrong!!!)
- ☞ History says that even well written programs still have 1-3 bugs per hundred statements.
- ☞ **Productivity and Quality in software:**
 - ❖ In production of consumer goods and other products, every manufacturing stage is subjected to quality control and testing from component to final stage.
 - ❖ If flaws are discovered at any stage, the product is either discarded or cycled back for rework and correction.
 - ❖ Productivity is measured by the sum of the costs of the material, the rework, and the discarded components, and the cost of quality assurance and testing.
 - ❖ There is a tradeoff between quality assurance costs and manufacturing costs: If sufficient time is not spent in quality assurance, the reject rate will be high and so will be the net cost. If inspection is good and all errors are caught as they occur, inspection costs will dominate, and again the net cost will suffer.
 - ❖ Testing and Quality assurance costs for 'manufactured' items can be as low as 2% in consumer products or as high as 80% in products such as space-ships, nuclear reactors, and aircrafts, where failures threaten life. Whereas the manufacturing cost of a software is trivial.
 - ❖ The biggest part of software cost is the cost of bugs: the cost of detecting them, the cost of correcting them, the cost of designing tests that discover them, and the cost of running those tests.
 - ❖ For software, quality and productivity are indistinguishable because the cost of a software copy is trivial.
- ☞ Testing and Test Design are parts of quality assurance should also focus on bug prevention. *A prevented bug is better than a detected and corrected bug.*
- ☞ Phases in a tester's mental life can be categorized into the following 5 phases:
 1. **Phase 0: (Until 1956: Debugging Oriented)** There is no difference between testing and debugging. Phase 0 thinking was the norm in early days of software development till testing emerged as a discipline.
 2. **Phase 1: (1957-1978: Demonstration Oriented)** The purpose of testing here is to show that software works. Highlighted during the late 1970s. This failed because the probability of showing that software works 'decreases' as testing increases. *i.e.* The more you test, the more likely you'll find a bug.
 3. **Phase 2: (1979-1982: Destruction Oriented)** The purpose of testing is to show that software doesn't work. This also failed because the software will never get released as you will find one bug or the other. Also, a bug corrected may also lead to another bug.
 4. **Phase 3: (1983-1987: Evaluation Oriented)** The purpose of testing is not to prove anything but to reduce the perceived risk of not working to an acceptable value (Statistical Quality Control). Notion is that testing does improve the product to the extent that testing catches bugs and to the extent that those bugs are fixed. The product is released when the confidence on that product is high enough. (Note: This is applied to large software products with millions of code and years of use.)
 5. **Phase 4: (1988-2000: Prevention Oriented)** Testability is the factor considered here. One reason is to reduce the labour of testing. Other reason is to check the testable and non-testable code. Testable code has fewer bugs than the code that's hard to test. Identifying the testing techniques to test the code is the main key here.

Test Design: We know that the software code must be designed and tested, but many appear to be unaware that tests themselves must be designed and tested. Tests should be properly designed and tested before applying it to the actual code.

Testing isn't everything: There are approaches other than testing to create better software. Methods other than testing include:

1. **Inspection Methods:** Methods like walkthroughs, deskchecking, formal inspections and code reading appear to be as effective as testing but the bugs caught do not completely overlap.
2. **Design Style:** While designing the software itself, adopting stylistic objectives such as testability, openness and clarity can do much to prevent bugs.
3. **Static Analysis Methods:** Includes formal analysis of source code during compilation. In earlier days, it is a routine job of the programmer to do that. Now, the compilers have taken over that job.
4. **Languages:** The source language can help reduce certain kinds of bugs. Programmers find new bugs while using new languages.
5. **Development Methodologies and Development Environment:** The development process and the environment in which that methodology is embedded can prevent many kinds of bugs.

DICHOTOMIES

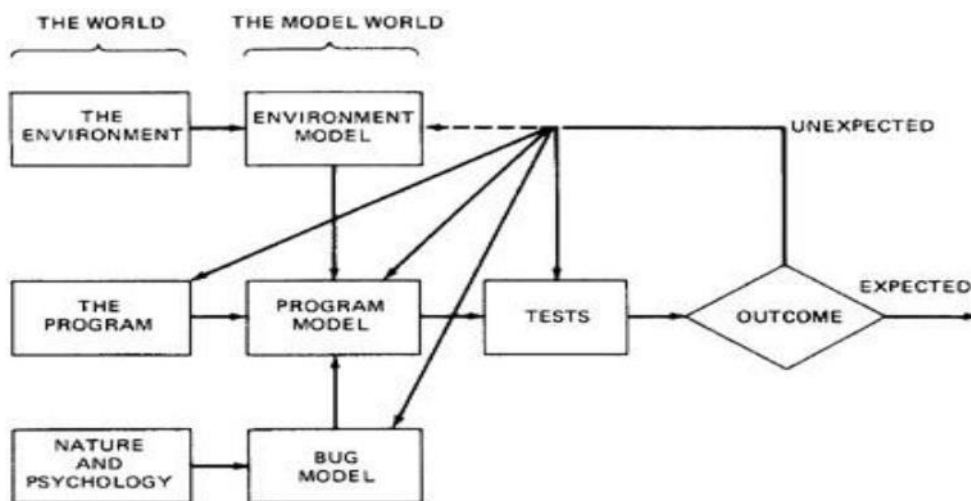

- Σ **Testing Versus Debugging:** Many people consider both as same. Purpose of testing is to show that a program has bugs. The purpose of testing is to find the error or misconception that led to the program's failure and to design and implement the program changes that correct the error.
- Σ Debugging usually follows testing, but they differ as to goals, methods and most important psychology. The below table shows few important differences between testing and debugging.

Testing	Debugging
Testing starts with known conditions, uses predefined procedures and has predictable outcomes.	Debugging starts from possibly unknown initial conditions and the end can not be predicted except statistically.
Testing can and should be planned, designed and scheduled.	Procedure and duration of debugging cannot be so constrained.
Testing is a demonstration of error or apparent correctness.	Debugging is a deductive process.
Testing proves a programmer's failure.	Debugging is the programmer's vindication (Justification).
Testing, as executes, should strive to be predictable, dull, constrained, rigid and inhuman.	Debugging demands intuitive leaps, experimentation and freedom.
Much testing can be done without design knowledge.	Debugging is impossible without detailed design knowledge.
Testing can often be done by an outsider.	Debugging must be done by an insider.
Much of test execution and design can be automated.	Automated debugging is still a dream.

- Σ **Function versus Structure:** Tests can be designed from a functional or a structural point of view. **Functional testing**, the program or system is treated as a black box. It is subjected to inputs, and its outputs are verified for conformance to specified behaviour. Functional testing takes the user point of view- both about functionality and features and not the program's implementation. **Structural testing** does look at the implementation details. Things such as programming style, control method, source language, database design, and coding details dominate structural testing.

- Σ Both Structural and functional tests are useful, both have limitations, and both target different kinds of bugs. Functional tests can detect all bugs but would take infinite time to do so. Structural tests are inherently finite but cannot detect all errors even if completely executed.
- Σ **Designer Versus Tester:** Test designer is the person who designs the tests whereas the tester is the one actually testing the code. During functional testing, the designer and tester are probably different persons. During unit testing, the tester and the programmer merge into one person.
- Σ Tests designed and executed by the software designers are by nature biased towards structural consideration and therefore suffer the limitations of structural testing.
- Σ **Modularity Versus Efficiency:** A module is a discrete, well-defined, small component of a system. Smaller the modules, difficult to integrate; larger the modules, difficult to understand. Both tests and systems can be modular. Testing can and should likewise be organised into modular components. Small, independent test cases can be designed to test independent modules.
- Σ **Small versus Large:** Programming in large means constructing programs that consist of many components written by many different programmers. Programming in the small is what we do for ourselves in the privacy of our own offices. Qualitative and Quantitative changes occur with size and so must testing methods and quality criteria.
- Σ **Builder Versus Buyer:** Most software is written and used by the same organization. Unfortunately, this situation is dishonest because it clouds accountability. If there is no separation between builder and buyer, there can be no accountability.
- Σ The different roles / users in a system include:
 1. **Builder:** Who designs the system and is accountable to the buyer.
 2. **Buyer:** Who pays for the system in the hope of profits from providing services.
 3. **User:** Ultimate beneficiary or victim of the system. The user's interests are also guarded by.
 4. **Tester:** Who is dedicated to the builder's destruction.
 5. **Operator:** Who has to live with the builders' mistakes, the buyers' murky (unclear) specifications, testers' oversights and the users' complaints.

MODEL FOR TESTING:

Above figure is a model of testing process. It includes three models: A model of the environment, a model of the program and a model of the expected bugs.

Σ **ENVIRONMENT:**

- ❖ A Program's environment is the hardware and software required to make it run. For online systems, the environment may include communication lines, other systems, terminals and operators.
- ❖ The environment also includes all programs that interact with and are used to create the program under test - such as OS, linkage editor, loader, compiler, utility routines.

- ❖ Because the hardware and firmware are stable, it is not smart to blame the environment for bugs.

Σ PROGRAM:

- ❖ Most programs are too complicated to understand in detail.
- ❖ The concept of the program is to be simplified in order to test it.
- ❖ If simple model of the program does not explain the unexpected behaviour, we may have to modify that model to include more facts and details. And if that fails, we may have to modify the program.

Σ BUGS:

- ❖ Bugs are more insidious (deceiving but harmful) than ever we expect them to be.
- ❖ An unexpected test result may lead us to change our notion of what a bug is and our model of bugs.
- ❖ Some optimistic notions that many programmers or testers have about bugs are usually unable to test effectively and unable to justify the dirty tests most programs need.
- ❖ **OPTIMISTIC NOTIONS ABOUT BUGS:**
 1. **Benign Bug Hypothesis:** The belief that bugs are nice, tame and logical. (Benign: Not Dangerous)
 2. **Bug Locality Hypothesis:** The belief that a bug discovered within a component affects only that component's behaviour.
 3. **Control Bug Dominance:** The belief that errors in the control structures (if, switch etc) of programs dominate the bugs.
 4. **Code / Data Separation:** The belief that bugs respect the separation of code and data.
 5. **Lingua Salvator Est:** The belief that the language syntax and semantics (e.g. Structured Coding, Strong typing, etc) eliminates most bugs.
 6. **Corrections Abide:** The mistaken belief that a corrected bug remains corrected.
 7. **Silver Bullets:** The mistaken belief that X (Language, Design method, representation, environment) grants immunity from bugs.
 8. **Sadism Suffices:** The common belief (especially by independent tester) that a sadistic streak, low cunning, and intuition are sufficient to eliminate most bugs. Tough bugs need methodology and techniques.
 9. **Angelic Testers:** The belief that testers are better at test design than programmers are at code design.

Σ TESTS:

- ❖ Tests are formal procedures, Inputs must be prepared, Outcomes should be predicted, tests should be documented, commands need to be executed, and results are to be observed. *All these errors are subjected to error*
- ❖ **We do three distinct kinds of testing on a typical software system. They are:**
 1. **Unit / Component Testing:** A **Unit** is the smallest testable piece of software that can be compiled, assembled, linked, loaded etc. A unit is usually the work of one programmer and consists of several hundred or fewer lines of code. **Unit Testing** is the testing we do to show that the unit does not satisfy its functional specification or that its implementation structure does not match the intended design structure. A **Component** is an integrated aggregate of one or more units. **Component Testing** is the testing we do to show that the component does not satisfy its functional specification or that its implementation structure does not match the intended design structure.
 2. **Integration Testing:** **Integration** is the process by which components are aggregated to create larger components. **Integration Testing** is testing done to show that even though the components were individually satisfactory (after passing component testing), checks the combination of components are incorrect or inconsistent.
 3. **System Testing:** A **System** is a big component. **System Testing** is aimed at revealing bugs that cannot be attributed to components. It includes testing for performance, security, accountability, configuration sensitivity, startup and recovery.

- Σ **Role of Models:** The art of testing consists of creating , selecting, exploring, and revising models. Our ability to go through this process depends on the number of different models we have at hand and their ability to express a program's behaviour.
-

CONSEQUENCES OF BUGS

- Σ **IMPORTANCE OF BUGS:** The importance of bugs depends on frequency, correction cost, installation cost, and consequences.

1. **Frequency:** How often does that kind of bug occur? Pay more attention to the more frequent bug types.
2. **CorrectionCost:** What does it cost to correct thebug afterit is found?Thecost is the sum of 2factors: (1) the cost of discovery (2) the cost of correction. These costs go up dramatically later in the development cycle when the bug is discovered. Correction cost also depends on system size.
3. **Installation Cost:** Installation cost depends on the number of installations: small for a single user program but more for distributed systems. Fixing one bug and distributing the fix could exceed the entire system's development cost.
4. **Consequences:** What aretheconsequencesofthebug? Bugconsequencescanrange frommildtocatastrophic. A reasonable metric for bug importance is

$$\text{Importance}=(\$)=\text{Frequency}*(\text{Correctioncost}+\text{Installation cost}+\text{Consequential cost})$$

- Σ **CONSEQUENCES OF BUGS:** The consequences of a bug can be measure in terms of human rather than machine. Some consequences of a bug on a scale of one to ten are:

1. **Mild:** The symptoms of the bug offend us aesthetically (gently); a misspelled output or a misaligned printout.
2. **Moderate:** Outputs are misleading or redundant. The bug impacts the system's performance.
3. **Annoying:** The system's behavior because of the bug is dehumanizing. *E.g.* Names are truncated or arbitrarily modified.
4. **Disturbing:** It refuses to handle legitimate (authorized / legal) transactions. The ATM wont give you money. My credit card is declared invalid.
5. **Serious:** It loses track of its transactions. Not just the transaction itself but the fact that the transaction occurred. Accountability is lost.
6. **Very Serious:** The bug causes the system to do the wrong transactions. Instead of losing your paycheck, the system credits it to another account or converts deposits to withdrawals.
7. **Extreme:** The problems aren't limited to a few users or to few transaction types. They are frequent and arbitrary instead of sporadic infrequent) or for unusual cases.
8. **Intolerable:** Long term unrecoverable corruption of the database occurs and the corruption is not easily discovered. Serious consideration is given to shutting the system down.
9. **Catastrophic:** The decision to shut down is taken out of our hands because the system fails.
10. **Infectious:** What can be worse than a failed system? One that corrupt other systems even though it does not fall in itself; that erodes the social physical environment; that melts nuclear reactors and starts war.

- Σ **FLEXIBLE SEVERITY RATHER THAN ABSOLUTES:**

- Quality can be measured as a combination of factors, of which number of bugs and their severity is only one component.
- Many organizations have designed and used satisfactory, quantitative, quality metrics.
- Because bugs and their symptoms play a significant role in such metrics, as testing progresses, you see the quality rise to a reasonable value which is deemed to be safe to ship the product.
- The factors involved in bug severity are:
 1. **Correction Cost:** Not so important because catastrophic bugs may be corrected easier and small bugs may take major time to debug.
 2. **Context and Application Dependency:** Severity depends on context and the application in which it is used.
 3. **Creating Culture Dependency:** Whats important depends on the creators of software and their cultural aspirations. Test tool vendors are more sensitive about bugs in their software than game software

vendors.

4. **User Culture Dependency:** Severity also depends on user culture. Naive users of PC software go crazy over bugs where as pros (experts) may just ignore.
 5. **The software development phase:** Severity depends on development phase. Any bug gets more severe as it gets closer to field use and more severe the longer it has been around.
-

TAXONOMY OF BUGS:

- Σ There is no universally correct way to categorize bugs. The taxonomy is not rigid.
- Σ A given bug can be put into one or another category depending on its history and the programmer's state of mind.
- Σ The major categories are: (1) Requirements, Features and Functionality Bugs (2) Structural Bugs (3) Data Bugs (4) Coding Bugs (5) Interface, Integration and System Bugs (6) Test and Test Design Bugs.

Requirements, Features And Functionality Bugs:

Various categories in Requirements, Features and Functionality bugs include:

1. Requirements and Specifications Bugs:

- ← Requirements and specifications developed from them can be incomplete, ambiguous, or self-contradictory. They can be misunderstood or impossible to understand.
- ← The specifications that don't have flaws in them may change while the design is in progress. The features are added, modified and deleted.
- ← Requirements, especially, as expressed in specifications are a major source of expensive bugs.
- ← The range is from a few percentage to more than 50%, depending on the application and environment.
- ← What hurts most about the bugs is that they are the earliest to invade the system and the last to leave.

2. Feature Bugs:

- ← Specification problems usually create corresponding feature problems.
- ← A feature can be wrong, missing, or superfluous (serving no useful purpose). A missing feature or case is easier to detect and correct. A wrong feature could have deep design implications.
- ← Removing the features might complicate the software, consume more resources, and foster more bugs.

3. Feature Interaction Bugs:

- ← Providing correct, clear, implementable and testable feature specifications is not enough.
- ← Features usually come in groups or related features. The features of each group and the interaction of features within the group are usually well tested.
- ← The problem is unpredictable interactions between feature groups or even between individual features. For example, your telephone is provided with call holding and call forwarding. The interactions between these two features may have bugs.
- ← Every application has its peculiar set of features and a much bigger set of unspecified feature interaction potentials and therefore result in feature interaction bugs.

Specification and Feature Bug Remedies:

- ← Most feature bugs are rooted in human to human communication problems. One solution is to use high-level, formal specification languages or systems.
- ← Such languages and systems provide short term support but in the long run, does not solve the problem.
- ← **Short term Support:** Specification languages facilitate formalization of requirements and inconsistency and ambiguity analysis.
- ← **Longterm Support:** Assume that we have a great specification language and that can be used to create unambiguous, complete specifications with unambiguous complete tests and consistent test criteria. The specification problem has been shifted to a higher level but not eliminated.

Testing Techniques for functional bugs: Most functional test techniques- that is those techniques which are based on a behavioral description of software, such as transaction flow testing, syntax testing, domain testing, logic testing and state testing are useful in testing functional bugs.

Structural Bugs: Various categories in Structural bugs include:

1. Control and Sequence Bugs:

- ← Control and sequence bugs include paths left out, unreachable code, improper nesting of loops, loop-back or loop termination criteria incorrect, missing process steps, duplicated processing, unnecessary processing, rampaging, GOTO's, ill-conceived (not properly planned) switches, spaghetti code, and worst of all, pachinko code.
- ← One reason for control flow bugs is that this area is amenable (supportive) to theoretical treatment.
- ← Most of the control flow bugs are easily tested and caught in unit testing.
- ← Another reason for control flow bugs is that use of old code especially ALP & COBOL code are dominated by control flow bugs.
- ← Control and sequence bugs at all levels are caught by testing, especially structural testing, more specifically path testing combined with a bottom line functional test based on a specification.

2. Logic Bugs:

- ← Bugs in logic, especially those related to misunderstanding how case statements and logic operators behave singly and combinations
- ← Also includes evaluation of boolean expressions in deeply nested IF-THEN-ELSE constructs.
- ← If the bugs are parts of logical (i.e. boolean) processing not related to control flow, they are characterized as processing bugs.
- ← If the bugs are parts of a logical expression (i.e. control-flow statement) which is used to direct the control flow, then they are categorized as control-flow bugs.

3. Processing Bugs:

- ← Processing bugs include arithmetic bugs, algebraic, mathematical function evaluation, algorithm selection and general processing.
- ← Examples of Processing bugs include: Incorrect conversion from one data representation to other, ignoring overflow, improper use of greater-than-or-equal etc
- ← Although these bugs are frequent (12%), they tend to be caught in good unit testing.

4. Initialization Bugs:

- ← Initialization bugs are common. Initialization bugs can be improper and superfluous.
- ← Superfluous bugs are generally less harmful but can affect performance.
- ← Typical initialization bugs include: Forgetting to initialize the variables before first use, assuming that they are initialized elsewhere, initializing to the wrong format, representation or type etc
- ← Explicit declaration of all variables, as in Pascal, can reduce some initialization problems.

5. Data-Flow Bugs and Anomalies:

- ← Most initialization bugs are special case of data flow anomalies.
- ← A data flow anomaly occurs where there is a path along which we expect to do something unreasonable with data, such as using an uninitialized variable, attempting to use a variable before it exists, modifying and then not storing or using the result, or initializing twice without an intermediate use.

Data bugs:

- ← Data bugs include all bugs that arise from the specification of data objects, their formats, the number of such objects, and their initial values.
- ← Data Bugs are at least as common as bugs in code, but they are often treated as if they did not exist at all.
- ← Code migrates data: Software is evolving towards programs in which more and more of the control and processing functions are stored in tables.
- ← Because of this, there is an increasing awareness that bugs in code are only half the battle and the data problems should be given equal attention.
- ← Dynamic Data Vs Static data:
 - ← Dynamic data are transitory. Whatever their purpose their lifetime is relatively short, typically the processing time of one transaction. A storage object may be used to hold dynamic data of different types, with different formats, attributes and residues.

- ← Dynamic data bugs are due to leftover garbage in a shared resource. This can be handled in one of the three ways: (1) Clean up after the use by the user (2) Common Cleanup by the resource manager (3) No Clean up
- ← Static Data are fixed in form and content. They appear in the source code or database directly or indirectly, for example a number, a string of characters, or a bit pattern.
- ← Compile time processing will solve the bugs caused by static data.
- ← Information, parameter, and control: Static or dynamic data can serve in one of three roles, or in combination of roles: as a parameter, for control, or for information.
- ← **Content, Structure and Attributes**: **Content** can be an actual bit pattern, character string, or number put into a data structure. Content is a pure bit pattern and has no meaning unless it is interpreted by a hardware or software processor. All data bugs result in the corruption or misinterpretation of content. **Structure** relates to the size, shape and numbers that describe the data object, that is memory location used to store the content. (e.g. A two dimensional array). **Attributes** relates to the specification meaning that is the semantics associated with the contents of a data object. (e.g. an integer, an alphanumeric string, a subroutine). *The severity and subtlety of bugs increases as we go from content to attributes because the things get less formal in that direction.*

Coding bugs:

- ← Coding errors of all kinds can create any of the other kind of bugs.
- ← Syntax errors are generally not important in the scheme of things if the source language translator has adequate syntax checking.
- ← If a program has many syntax errors, then we should expect many logic and coding bugs.
- ← The documentation bugs are also considered as coding bugs which may mislead the maintenance programmers.

Interface, integration, and system bugs:

- ← Various categories of bugs in Interface, Integration, and System Bugs are:

External Interfaces:

- ← The external interfaces are the means used to communicate with the world.
- ← These include devices, actuators, sensors, input terminals, printers, and communication lines.
- ← The primary design criterion for an interface with outside world should be robustness.
- ← All external interfaces, human or machine should employ a protocol. The protocol may be wrong or incorrectly implemented.
- ← Other external interface bugs are: invalid timing or sequence assumptions related to external signals
- ← Misunderstanding external input or output formats.
- ← Insufficient tolerance to bad input data.

Internal Interfaces:

- ← Internal interfaces are in principle not different from external interfaces but they are more controlled.
- ← A best example for internal interfaces are communicating routines.
- ← The external environment is fixed and the system must adapt to it but the internal environment, which consists of interfaces with other components, can be negotiated.
- ← Internal interfaces have the same problem as external interfaces.

Hardware Architecture:

- ← Bugs related to hardware architecture originate mostly from misunderstanding how the hardware works.
- ← Examples of hardware architecture bugs: address generation error, i/o device operation / instruction error, waiting too long for a response, incorrect interrupt handling etc.
- ← The remedy for hardware architecture and interface problems is two fold: (1) Good Programming and Testing (2) Centralization of hardware interface software in programs written by hardware interface specialists.

Operating System Bugs:

- ← Program bugs related to the operating system are a combination of hardware architecture and interface bugs mostly caused by a misunderstanding of what it is the operating system does.
- ← Use operating system interface specialists, and use explicit interface modules or macros for all operating system

calls.

- ← This approach may not eliminate the bugs but at least will localize them and make testing easier.

Software Architecture:

- ← Software architecture bugs are the kind that called - interactive.
- ← Routines can pass unit and integration testing without revealing such bugs.
- ← Many of them depend on load, and their symptoms emerge only when the system is stressed.
- ← Sample for such bugs: Assumption that there will be no interrupts, Failure to block or un block interrupts, Assumption that memory and registers were initialized or not initialized etc
- ← Careful integration of modules and subjecting the final system to a stress test are effective methods for these bugs.

Control and Sequence Bugs (Systems Level):

- ← These bugs include: Ignored timing, Assuming that events occur in aspecified sequence, Working on data before all the data have arrived from disc, Waiting for an impossible combination of prerequisites, Missing, wrong, redundant or superfluous process steps.
- ← The remedy for these bugs is highly structured sequence control.
- ← Specialize, internal, sequence control mechanisms are helpful.

Resource Management Problems:

- ← Memory is subdivided into dynamically allocated resources such as buffer blocks, queue blocks, task control blocks, and overlaybuffers.
- ← External mass storage units such as discs, are subdivided into memory resource pools.
- ← Someresourcemanagement andusagebugs: Requiredresourcenotobtained, Wrongresource used, Resource is already in use, Resource dead lock etc
- ← Resource Management Remedies: A designremedy that prevents bugs is always preferable to a test method that discovers them.
- ← The design remedy in resource management is to keep the resource structure simple: the fewest different kinds of resources, the fewest pools, and no private resource management.

Integration Bugs:

- ← Integration bugs are bugs having to do with the integration of, and with the interfaces between, working and tested components.
- ← These bugs results from inconsistencies or incompatibilities between components.
- ← Thecommunicationmethodsincludedatastructures, callsequences, registers, semaphores, communication links and protocols results in integration bugs.
- ← The integration bugs do not constitute a big bug category(9%) they are expensive category because they are usually caught late in the game and because they force changes in several components and/or data structures.

System Bugs:

- ← System bugs covering all kinds of bugs that cannot be ascribed to a component or to their simple interactions, but result from the totality of interactions between many components such as programs, data, hardware, and the operating systems.
- ← There can be no meaningful system testing until there has been thorough component and integration testing.
- ← System bugs are infrequent(1.7%) but very important because they are often found only after the system has been fielded.

Test and test design bugs:

- ← Testing: testers have no immunity to bugs. Tests require complicated scenarios and databases.
- ← They require code or the equivalent to execute and consequently they can have bugs.
- ← Test criteria: if the specification is correct, it is incorrectly interpreted and implemented, and a proper test has been designed; but the criterion by which the software's behavior is judged may be incorrect or impossible. So, a proper test criteria has to be designed. The more complicated the criteria, the likelier they are to have bugs.

← **Remedies:** The remedies of test bugs are:

1. **Test Debugging:** The first remedy for test bugs is testing and debugging the tests. Test debugging, when compared to program debugging, is easier because tests, when properly designed are simpler than programs and donot have to make concessions to efficiency.
2. **Test Quality Assurance:** Programmers have the right to ask how quality in independent testing is monitored.
3. **Test Execution Automation:** The history of software bug removal and prevention is indistinguishable from the history of programming automation aids. Assemblers, loaders, compilers are developed to reduce the incidence of programmingandoperationerrors.Test executionbugs arevirtually eliminatedby various testexecution automation tools.
4. **Test Design Automation:** Just asmuchofsoftwaredevelopment hasbeenautomated, much test designcanbe and has been automated.For a given productivity rate, automationreduces thebug count - be it for software or be it for tests.

FLOWGRAPHS AND PATH TESTING

Flow graphs and Path testing: Basics Concepts of Path Testing, Predicates, Path Predicates and Achievable Paths, Path Sensitizing, Path Instrumentation, Application of Path Testing.

BASICS CONCEPTS OF PATH TESTING:

Path Testing:

- Σ Path Testing is the name given to a family of test techniques based on judiciously selecting a set of test paths through the program.
- Σ If the set of paths are properly chosen then we have achieved some measure of test thoroughness. For example, pick enough paths to assure that every source statement has been executed at least once.
- Σ Path testing techniques are the oldest of all structural test techniques.
- Σ Path testing is most applicable to new software for unit testing. It is a structural technique.
- Σ It requires complete knowledge of the program's structure.
- Σ It is most often used by programmers to unit test their own code.
- Σ The effectiveness of path testing rapidly deteriorates as the size of the software aggregate under test increases.

The bug assumption:

- Σ **The bug assumption** for the path testing strategies is that something has gone wrong with the software that makes it take a different path than intended.
- Σ As an example "GOTO X" where "GOTO Y" had been intended.
- Σ Structured programming languages prevent many of the bugs targeted by path testing: as a consequence the effectiveness for path testing for these languages is reduced and for old code in COBOL, ALP, FORTRAN and Basic, the path testing is indispensable.

Control flow graphs:

- Σ The control flow graph is a graphical representation of a program's control structure. It uses the elements named process blocks, decisions, and junctions.
- Σ The flow graph is similar to the earlier flowchart, with which it is not to be confused.
- Σ **Flow Graph Elements** : A flow graph contains four different types of elements. (1) Process Block (2) Decisions (3) Junctions (4) Case Statements

1. Process Block:

- ← A process block is a sequence of program statements uninterrupted by either decisions or junctions.
- ← It is a sequence of statements such that if any one of the statements of the block is executed, then all statements thereof are executed.
- ← Formally, a process block is a piece of straight line code of one statement or hundreds of statements.
- ← A process has one entry and one exit. It can consist of a single statement or instruction, a sequence of statements or instructions, a single entry/exit subroutine, a macro or function call, or a sequence of these.

2. Decisions:

- ← A decision is a program point at which the control flow can diverge.
- ← Machine language conditional branch and conditional skip instructions are examples of decisions.
- ← Most of the decisions are two-way but some are three-way branches in control flow.

3. Case Statements:

- ← A case statement is a multi-way branch or decisions.
- ← Examples of case statement are a jump table in assembly language, and the PASCAL case statement.
- ← From the point of view of test design, there are no differences between Decisions and Case Statements

4. Junctions:

- ← A junction is a point in the program where the control flow can merge.
- ← Examples of junctions are: the target of a jump or skip instruction in ALP, a label that is a target of GOTO.

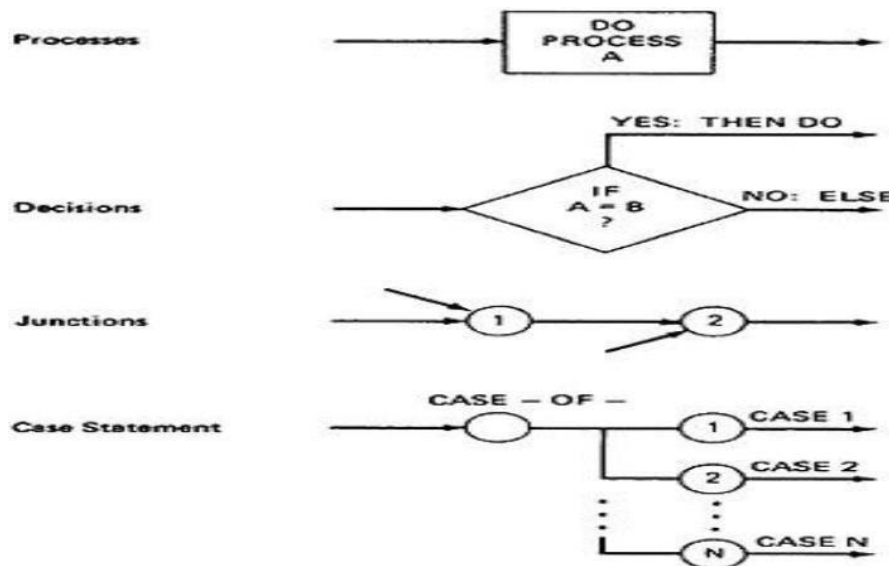

Figure: Flow graph Elements

Control flow graphs vs flowcharts:

- Σ A program's flow chart resembles a control flow graph.
- Σ In flow graphs, we don't show the details of what is in a process block.
- Σ In flow charts every part of the process block is drawn.
- Σ The flowchart focuses on process steps, whereas the flow graph focuses on control flow of the program.
- Σ The act of drawing a control flow graph is a useful tool that can help us clarify the control flow and data flow issues.

Notational evolution:

- Σ The control flow graph is simplified representation of the program's structure.
- Σ The notation changes made in creation of control flow graphs:
 - The process boxes weren't really needed. There is an implied process on every line joining junctions and decisions.
 - We don't need to know the specifics of the decisions, just the fact that there is a branch.
 - The specific target label names aren't important-just the fact that they exist. So we can replace them by simple numbers.
 - To understand this, we will go through an example written in a FORTRAN like programming language called **Programming Design Language (PDL)**. The program's corresponding flowchart and flowgraph were also provided below for better understanding.

```

CODE* (PDL)

INPUT X, Y
Z := X + Y
V := X - Y
IF Z >= 0 GOTO SAM
JOE: Z := Z - 1
SAM: Z := Z + V
FOR U = 0 TO Z
  V(U), U(V) := (Z + V)*U
  IF V(U) = 0 GOTO JOE
  Z := Z - 1
  IF Z = 0 GOTO ELL
  U := U + 1
NEXT U

      V(U-1) := V(U+1) + U(V-1)
ELL: V(U+U(V)) := U + V
      IF U = V GOTO JOE
      IF U > V THEN U := Z
      Z := U
      END

* A contrived horror

```

Figure: Program Example (PDL)

○ The first step in translating the program to a flowchart is shown, where we have the typical one-for-one classical flowchart. Note that complexity has increased, clarity has decreased, and that we had to add auxiliary labels (LOOP, XX, and YY), which have no actual program counterpart. We merged the process steps and replaced them with the single process box. We now have a control flow graph. But this representation is still too busy. We simplify the notation further where for the first time we can really see what the control flow looks like.

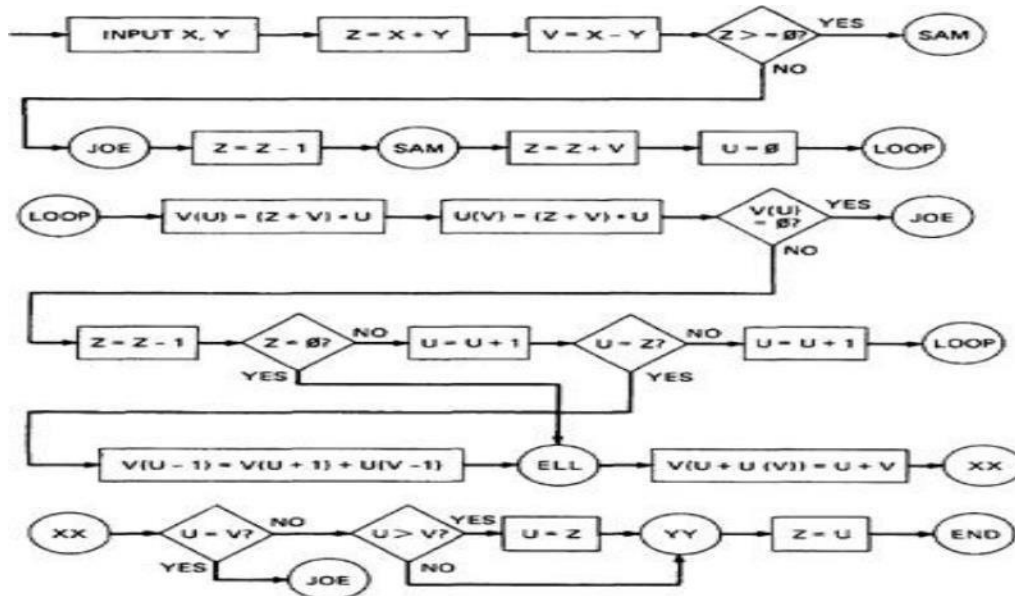

Figure: One-to-one flowchart for example program

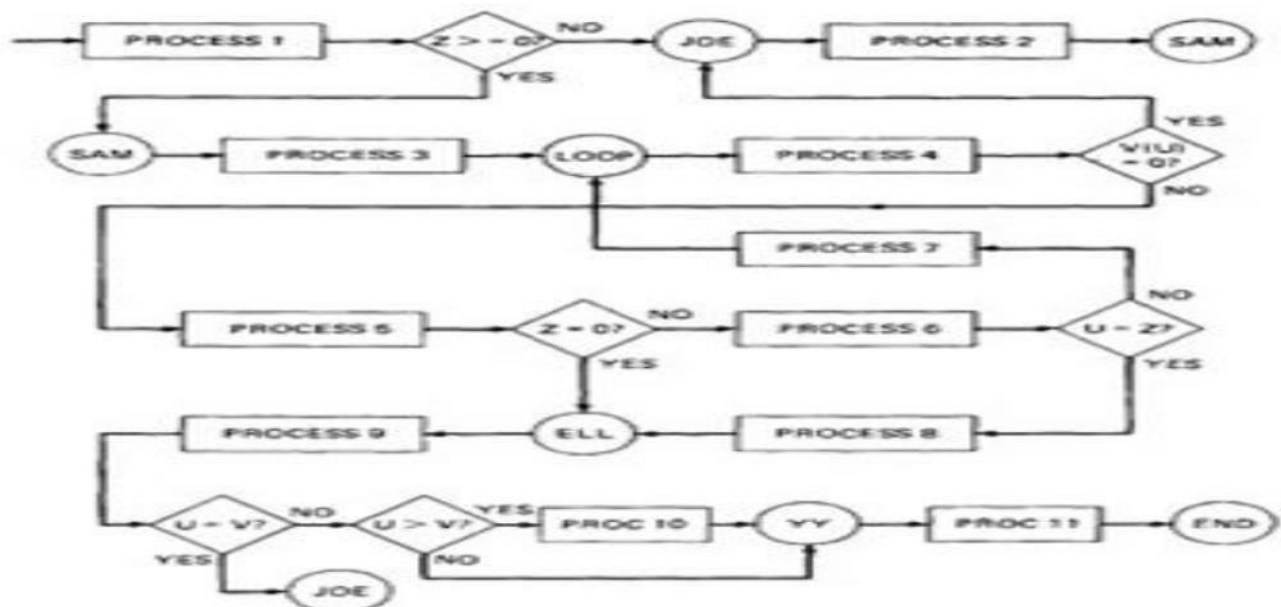

Figure: Control Flow graph for example

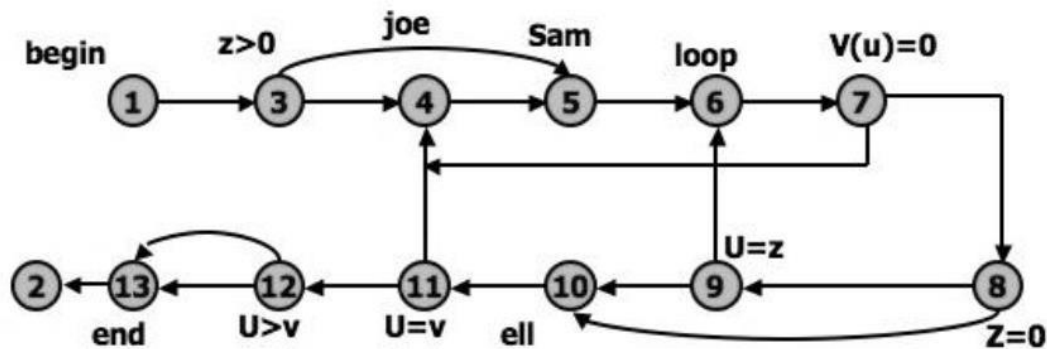

Figure: Simplified Flow graph Notation

Figure: Even Simplified Flow graph Notation

The final transformation is shown in Figure, where we've dropped the node numbers to achieve an even simpler representation. The way to work with control flow graphs is to use the simplest possible representation - that is, no more information than you need to correlate back to the source program or PDL.

Linked List Representation:

- Σ Although graphical representations of flow graphs are revealing, the details of the control flow inside a program they are often inconvenient.
- Σ In linked list representation, each node has a name and there is an entry on the list for each link in the flow graph. only the information pertinent to the control flow is shown.
- Σ Linked List representation of Flow Graph:

1 (BEGIN)	:	3	
2 (END)	:		Exit, no outlink
3 (Z>0?)	:	4 (FALSE)	
	:	5 (TRUE)	
4 (JOE)	:	6	
5 (SAM)	:	7	
6 (LOOP)	:	8 (TRUE)	
7 (V(U)=0?)	:	9 (FALSE)	
	:	10 (TRUE)	
8 (Z=0?)	:	6 (FALSE) = LOOP	
	:	10 (TRUE) = ELL	
9 (U=Z?)	:	11	
10 (ELL)	:	4 (TRUE) = JOE	
11 (U=V?)	:	12 (FALSE)	
12 (U>V?)	:	13 (TRUE)	
	:	13 (FALSE)	
13	:	2 (END)	

Figure: Linked List Control Flow graph Notation

Flow graph - program correspondence:

- Σ A flow graph is a pictorial representation of a program and not the program itself, just as a topographic map.
- Σ You can't always associate the parts of a program in a unique way with flow graph parts because many program structures, such as if-then-else constructs, consist of a combination of decisions, junctions, and processes.
- Σ The translation from a flow graph element to a statement and vice versa is not always unique.

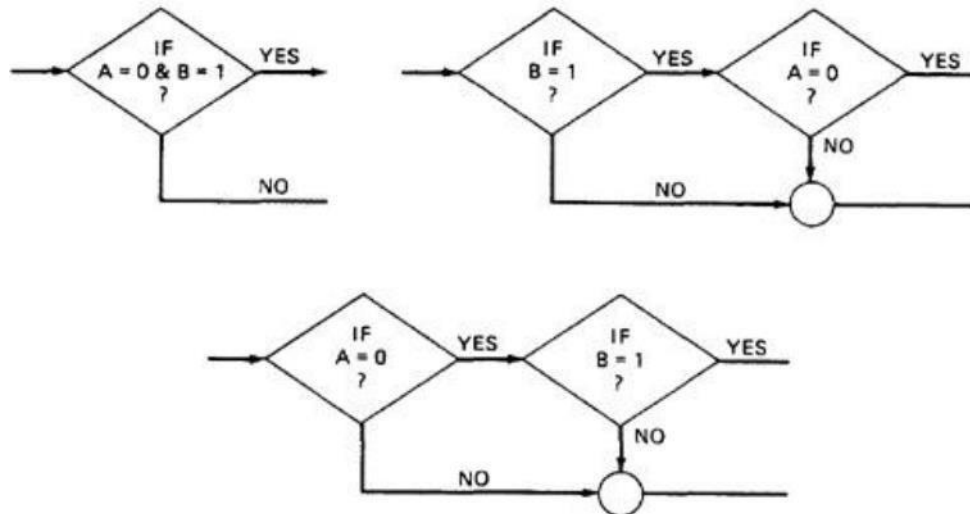

Figure: Alternative Flow graphs for same logic (Statement "IF (A=0) AND (B=1) THEN . . .").

- Σ An improper translation from flow graph to code during coding can lead to bugs, and improper translation during the test design lead to missing test cases and causes undiscovered bugs.

Flow graph and flowchart generation:

- Σ Flowcharts can be
 1. Handwritten by the programmer.
 2. Automatically produced by a flowcharting program based on a mechanical analysis of the source code.
 3. Semi automatically produced by a flow charting program based in part on structural analysis of the source code and in part on directions given by the programmer.
- Σ There are relatively few control flow graph generators.

Path testing - paths, nodes and links:

- Σ **Path:** A path through a program is a sequence of instructions or statements that starts at an entry, junction, or decision and ends at another, or possibly the same junction, decision, or exit.
- Σ A path may go through several junctions, processes, or decisions, one or more times.
- Σ A path consists of segments.
- Σ The **segment** is a link - a single process that lies between two nodes.
- Σ A **path segment** is succession of consecutive links that belongs to some path.
- Σ The length of path measured by the number of links in it and not by the number of the instructions or statements executed along that path.
- Σ The name of a path is the name of the nodes along the path.

Fundamental path selection criteria:

- Σ There are many paths between the entry and exit of a typical routine.
- Σ Every decision doubles the number of potential paths. And every loop multiplies the number of potential paths by the number of different iteration values possible for the loop.

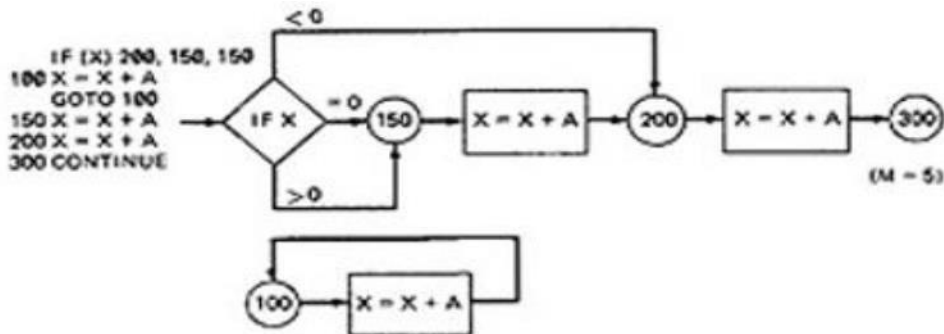

- Σ Defining complete testing:
 1. Exercise every path from entry to exit
 2. Exercise every statement or instruction at least once
 3. Exercise every branch and case statement, in each direction at least once
- Σ If prescription 1 is followed then 2 and 3 are automatically followed. But it is impractical for most routines. It can be done for the routines that have no loops, in which it is equivalent to 2 and 3 prescriptions.
- Σ **EXAMPLE:** Here is the correct version.

For X negative, the output is X + A, while for X greater than or equal to zero, the output is X + 2A. Following prescription 2 and executing every statement, but not every branch, would not reveal the bug in the following incorrect version:

A negative value produces the correct answer. Every statement can be executed, but if the test cases do not force each branch to be taken, the bug can remain hidden. The next example uses a test based on executing each branch but does not force the execution of all statements:

- Σ The hidden loop around label 100 is not revealed by tests based on prescription 3 alone because no test forces the execution of statement 100 and the following GOTO statement. Furthermore, label 100 is not flagged by the compiler as an unreferenced label and the subsequent GOTO does not refer to an undefined label.
- Σ A **Static Analysis** (that is, an analysis based on examining the source code or structure) cannot determine whether a piece of code is or is not reachable. There could be subroutine calls with parameters that are subroutine labels, or in the above example there could be a GOTO that targeted label 100 but could never achieve a value that would send the program to that label.
- Σ Only a **Dynamic Analysis** (that is, an analysis based on the code's behavior while running - which is to say, to all intents and purposes, testing) can determine whether code is reachable or not and therefore distinguish between the ideal structure we think we have and the actual, buggy structure.

Path testing criteria:

- Σ Any testing strategy based on paths must at least both exercise every instruction and take branches in all directions.
- Σ A set of tests that does this is not complete in an absolute sense, but it is complete in the sense that anything less must leave something untested.
- Σ So we have explored three different testing criteria or strategies out of a potentially infinite family of strategies.

1. **Path Testing (P_{∞}):**

- ← Execute all possible control flow paths through the program: typically, this is restricted to all possible entry/exit paths through the program.
- ← If we achieve this prescription, we are said to have achieved 100% path coverage. This is the strongest criterion in the path testing strategy family: it is generally impossible to achieve.

2. **Statement Testing (P_1):**

- ← Execute all statements in the program at least once under some test. If we do enough tests to achieve this, we are said to have achieved 100% statement coverage.
- ← An alternate equivalent characterization is to say that we have achieved 100% node coverage. We denote this by C1.
- ← This is the weakest criterion in the family: testing less than this for new software is unconscionable (unprincipled or can not be accepted) and should be criminalized.

3. **Branch Testing (P_2):**

- ← Execute enough tests to assure that every branch alternative has been exercised at least once under some test.
- ← If we do enough tests to achieve this prescription, then we have achieved 100% branch coverage.
- ← An alternative characterization is to say that we have achieved 100% link coverage.
- ← For structured software, branch testing and therefore branch coverage strictly includes statement coverage.
- ← We denote branch coverage by C2.

Common Sense and strategies:

- Branch and statement coverage are accepted today as the minimum mandatory testing requirement.
- The question "why not use a judicious sampling of paths?, what is wrong with leaving some code, untested?" is ineffectual in the view of common sense and experience since: **(1.)** Not testing a piece of a code leaves a residue of bugs in the program in proportion to the size of the untested code and the probability of bugs. **(2.)** The high probability paths are always thoroughly tested if only to demonstrate that the system works properly.

Which paths to be tested?

You must pick enough paths to achieve C1+C2. The question of what is the fewest number of such paths is interesting to the designer of test tools that help automate the path testing, but it is not crucial to the pragmatic (practical) design of tests. It is better to make many simple paths than a few complicated paths.

Figure: An example flow graph to explain path selection

Practical Suggestions in Path Testing:

1. Draw the control flow graph on a single sheet of paper.
2. Make several copies - as many as you will need for coverage (C1+C2) and several more.
3. Use a yellow highlighting marker to trace paths. Copy the paths onto a master sheets.
4. Continue tracing paths until all lines on the master sheet are covered, indicating that you appear to have achieved C1+C2.
5. As you trace the paths, create a table that shows the paths, the coverage status of each process, and each decision.
6. The above paths lead to the following table considering Figure:

PATHS	DECISIONS				PROCESS-LINK												
	4	6	7	9	a	b	c	d	e	f	g	h	i	j	k	l	m
abcde	YES	YES			✓	✓	✓	✓	✓								
abhkgde	NO	YES		NO	✓	✓		✓	✓		✓	✓			✓		
abhlibcde	NO,YES	YES		YES	✓	✓	✓	✓	✓			✓	✓			✓	
abcdfigde	YES	NO,YES	YES		✓	✓	✓	✓	✓	✓	✓			✓			
abcdfmibcde	YES	NO,YES	NO		✓	✓	✓	✓	✓	✓			✓				✓

After you have traced a covering path set on the master sheet and filled in the table for every path, check the following:

1. Does every decision have a YES and a NO in its column? (C2)
2. Has every case of all case statements been marked? (C2)
3. Is every three-way branch (less, equal, greater) covered? (C2)
4. Is every link (process) covered at least once? (C1)

Revised Path Selection Rules:

- Σ Pick the simplest, functionally sensible entry/exit path.
- Σ Pick additional paths as small variation from previous paths. Pick paths that do not have loops rather than paths that do. Favor short paths that make sense over paths that don't.
- Σ Pick additional paths that have no obvious functional meaning only if it's necessary to provide coverage.
- Σ Be comfortable with your chosen paths. Play your hunches (guesses) and give your intuition free reign as long as you achieve C1+C2.
- Σ Don't follow rules slavishly (blindly) - except for coverage.

Loops:

- Σ **Cases for a single loop:** A single loop can be covered with two cases: Looping and Not looping. But, experience shows that many loop-related bugs are not discovered by C1+C2. Bugs hide themselves in corners and congregate at boundaries - in the cases of loops, at or around the minimum or maximum number of times the loop can be iterated. The minimum number of iterations is often zero, but it need not be.

CASE 1: Single loop, Zero minimum, N maximum, No excluded values

1. Try bypassing the loop (zero iterations). If you can't, you either have a bug, or zero is not the minimum and you have the wrong case.
2. Could the loop-control variable be negative? Could it appear to specify a negative number of iterations? What happens to such a value?
3. One pass through the loop.
4. Two passes through the loop.
5. A typical number of iterations, unless covered by a previous test.

6. One less than the maximum number of iterations.
7. The maximum number of iterations.
8. Attempt one more than the maximum number of iterations. What prevents the loop-control variable from having this value? What will happen with this value if it is forced?

CASE 2: Single loop, Non-zero minimum, No excluded values

1. Try one less than the expected minimum. What happens if the loop control variable's value is less than the minimum? What prevents the value from being less than the minimum?
2. The minimum number of iterations.
3. One more than the minimum number of iterations.
4. Once, unless covered by a previous test.
5. Twice, unless covered by a previous test.
6. A typical value.
7. One less than the maximum value.
8. The maximum number of iterations.
9. Attempt one more than the maximum number of iterations.

CASE 3: Single loops with excluded values

- Treat single loops with excluded values as two sets of tests consisting of loops without excluded values, such as case 1 and 2 above.
- Example, the total range of the loop control variable was 1 to 20, but that values 7,8,9,10 were excluded. The two sets of tests are 1-6 and 11-20.
- The test cases to attempt would be 0,1,2,4,6,7 for the first range and 10,11,15,19,20,21 for the second range.

Kinds of Loops: There are only three kinds of loops with respect to path testing:

Nested Loops:

- ← The number of tests to be performed on nested loops will be the exponent of the tests performed on single loops.
- ← As we cannot always afford to test all combinations of nested loops' iterations values. Here's a tactic used to discard some of these values:
 1. Start at the inner most loop. Set all the outer loops to their minimum values.
 2. Test the minimum, minimum+1, typical, maximum-1, and maximum for the innermost loop, while holding the outer loops at their minimum iteration parameter values. Expand the tests as required for out of range and excluded values.
 3. If you've done the outermost loop, GOTO step 5, else move out one loop and set it up as in step 2 with all other loops set to typical values.
 4. Continue outward in this manner until all loops have been covered.
 5. Do all the cases for all loops in the nest simultaneously.

Concatenated Loops:

- ← Concatenated loops fall between single and nested loops with respect to test cases. Two loops are concatenated if it's possible to reach one after exiting the other while still on a path from entrance to exit.
- ← If the loops cannot be on the same path, then they are not concatenated and can be treated as individual loops.

Horrible Loops:

- ← A horrible loop is a combination of nested loops, the use of code that jumps into and out of loops, intersecting loops, hidden loops, and cross connected loops.
- ← Makes iteration value selection for test cases an awesome and ugly task, which is another reason such structures should be avoided.

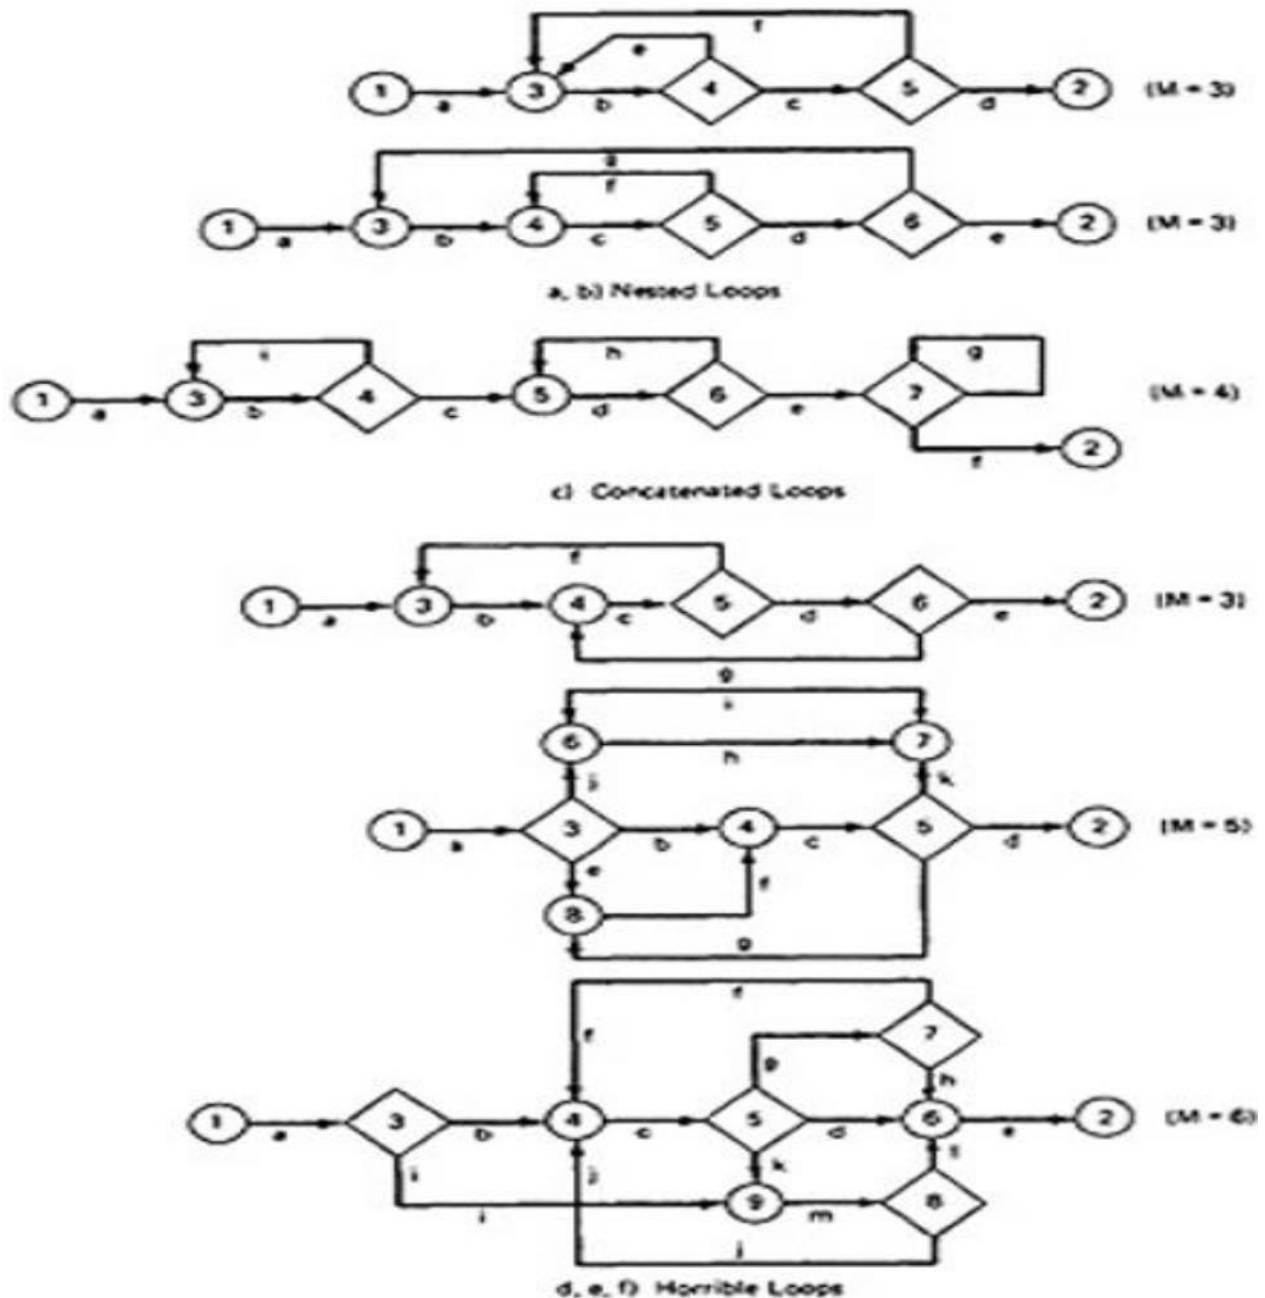

Figure: Example of Loop types

Loop Testing Time:

- Σ Any kind of loop can lead to long testing time, especially if all the extreme value cases are to be attempted (Max-1, Max, Max+1).
- Σ This situation is obviously worse for nested and dependent concatenated loops.
- Σ Consider nested loops in which testing the combination of extreme values lead to long test times. Several options to deal with:
 - Prove that the combined extreme cases are hypothetically possible, they are not possible in the real world
 - Put in limits or checks that prevent the combined extreme cases. Then you have to test the software that implements such safety measures.

PREDICATES, PATH PREDICATES AND ACHIEVABLE PATHS:

- Σ **Predicate:** The logical function evaluated at a decision is called Predicate. The direction taken at a decision depends on the value of decision variable. Some examples are: $A > 0$, $x + y \geq 90$
- Σ **Path Predicate:** A predicate associated with a path is called a Path Predicate. For example, "x is greater than zero", " $x + y \geq 90$ ", "whether negative or equal to 10 is true" is a sequence of predicates whose truth values will cause the routine to take a specific path.
- Σ **Multi way Branches:**
 - The path taken through a multi way branch such as a computed GOTO's, case statement, or jump tables cannot be directly expressed in TRUE/FALSE terms.
 - Although, it is possible to describe such alternatives by using multi valued logic, an expedient (practical approach) is to express multi way branches as an equivalent set of if..then. else statements.
 - For example a three way case statement can be written as: If case=1 DO A1 ELSE (IF Case=2 DO A2 ELSE DO A3 ENDIF)ENDIF.
- Σ **Inputs:**
 - Interestingly, the word input is not restricted to direct inputs, such as variables in a subroutine call, but includes all data objects referenced by the routine whose values are fixed prior to entering it.
 - For example, inputs in a calling sequence, objects in a data structure, values left in registers, or any combination of object types.
 - The input for a particular test is mapped as a one dimensional array called as an Input Vector.

Predicate Expressions

- Σ **Predicate interpretation:**
 - The simplest predicate depends only on input variables.
 - For example if x_1, x_2 are inputs, the predicate might be $x_1 + x_2 \geq 7$, given the values of x_1 and x_2 the direction taken through the decision is based on the predicate is determined at input time and does not depend on processing.
 - Another example, assume a predicate $x_1 + y \geq 0$ that along a path prior to reaching this predicate we had the assignment statement $y = x_2 + 7$. although our predicate depends on processing, we can substitute the symbolic expression for y to obtain an equivalent predicate $x_1 + x_2 + 7 \geq 0$.
 - The act of symbolic substitution of operations along the path in order to express the predicate solely in terms of the input vector is called **predicate interpretation**.

Some times the interpretation may depend on the path; for example,

```
INPUT X
ON X GOTO A, B, C, ...
A: Z := 7 @ GOTO HEM
B: Z := -7 @ GOTO HEM
C: Z := 0 @ GOTO HEM
```

```
.....
HEM: DO SOMETHING
```

```
.....
HEN: IF Y + Z > 0 GOTO ELL ELSE GOTO EMM
```

The predicate interpretation at HEN depends on the path we took through the first multi way branch. It yields for the three cases respectively, if $Y + 7 > 0$, $Y - 7 > 0$, $Y > 0$.

- The path predicates are the specific form of the predicates of the decisions along the selected path after interpretation.

Σ **Independence of variables and predicates:**

- The path predicates take on truth values based on the values of input variables, either directly or indirectly.
- If a variable's value does not change as a result of processing, that variable is independent of the processing.
- If the variable's value can change as a result of the processing, the variable is process dependent.
- A predicate whose truth value can change as a result of the processing is said to be **process dependent** and one whose truth value does not change as a result of the processing is **process independent**.
- Process dependence of a predicate does not always follow from dependence of the input variables on which that predicate is based.

Σ **Correlation Of Variables And Predicates:**

- Two variables are correlated if every combination of their values cannot be independently specified.
- Variables whose values can be specified independently without restriction are called uncorrelated.
- A pair of predicates whose outcomes depend on one or more variables in common are said to be correlated predicates.
For example, the predicate $X=Y$ is followed by another predicate $X+Y == 8$. If we select X and Y values to satisfy the first predicate, we might have forced the 2nd predicate's truth value to change.
- Every path through a routine is achievable only if all the predicates in that routine are uncorrelated.

Σ **Path predicate expressions:**

- A path predicate expression is a set of boolean expressions, all of which must be satisfied to achieve the selected path.
- Example:
 $X1+3X2+17 \geq 0$
 $X3=17$
 $X4-X1 \geq 14X2$

Any set of input values that satisfy all of the conditions of the path predicate expression will force the routine to the path.

Some times a predicate can have an OR in it.

Example:

A: $X5 > 0$ E: $X6 < 0$
 B: $X1 + 3X2 + 17 \geq 0$ B: $X1 + 3X2 + 17 \geq 0$
 C: $X3 = 17$ C: $X3 = 17$
 D: $X4 - X1 \geq 14X2$ D: $X4 - X1 \geq 14X2$

Boolean algebra notation to denote the boolean expression:

$$ABCD + EBCD = (A+E)BCD$$

Σ **Predicate coverage:**

- **Compound Predicate:** Predicates of the form $A \text{ OR } B$, $A \text{ AND } B$ and more complicated boolean expressions are called as compound predicates.
- Some times even a simple predicate becomes compound after interpretation. Example: the predicate if $(x=17)$ whose opposite branch is if $x \neq 17$ which is equivalent to $x > 17$. Or. $x < 17$.
- Predicate coverage is being the achieving of all possible combinations of truth values corresponding to the selected path have been explored under some test.
- As achieving the desired direction at a given decision could still hide bugs in the associated predicates.

Σ **Testing blindness:**

- Testing Blindness is a pathological (harmful) situation in which the desired path is achieved for the wrong reason.

- There are three types of Testing Blindness:

1. Assignment Blindness:

- ← Assignment blindness occurs when the buggy predicate appears to work correctly because the specific value chosen for an assignment statement works with both the correct and incorrect predicate.

← For Example:

Correct	Buggy
X = 7	X = 7
.....
if Y > 0 then ...	if X+Y > 0 then ...

- ← If the test case sets Y=1 the desired path is taken in either case, but there is still a bug.

2. Equality Blindness:

- ← Equality blindness occurs when the path selected by a prior predicate results in a value that works both for the correct and buggy predicate.
- ← For Example:

Correct	Buggy
if Y = 2 then	if Y = 2 then
.....
if X+Y > 3 then ...	if X > 1 then ...

- ← The first predicate if y=2 forces the rest of the path, so that for any positive value of x. the path taken at the second predicate will be the same for the correct and buggy version.

3. Self Blindness:

- ← Self blindness occurs when the buggy predicate is a multiple of the correct predicate and as a result is indistinguishable along that path.
- ← For Example:

Correct	Buggy
X=A	X=A
.....
if X-1 > 0 then ...	if X+A-2 > 0 then ...

- ← The assignment (x=a) makes the predicates multiples of each other, so the direction taken is the same for the correct and buggy version.

PATH SENSITIZING:

Σ **Review: achievable and unachievable paths:**

- We want to select and test enough paths to achieve a satisfactory notion of test completeness such as C1+C2.
- Extract the programs control flowgraph and select a set of tentative covering paths.

- For any path in that set, interpret the predicates along the path as needed to express them in terms of the input vector. In general individual predicates are compound or may become compound as a result of interpretation.
- Trace the path through, multiplying the individual compound predicates to achieve a boolean expression such as

$$(A+BC) (D+E) (FGH) (IJ) (K) (L) (L).$$

- Multiply out the expression to achieve a sum of products form:

$$ADFGHIJKL+AEFGHIJKL+BCDFGHIJKL+BCEFGHIJKL$$
- Each product term denotes a set of inequalities that if solved will yield an input vector that will drive the routine along the designated path.
- Solve any one of the inequality sets for the chosen path and you have found a set of input values for the path.
- If you can find a solution, then the path is achievable.
- If you cant find a solution to any of the sets of inequalities, the path is un achievable.
- The act of finding a set of solutions to the path predicate expression is called **PATH SENSITIZATION**.

Σ Heuristic procedures for sensitizing paths:

- This is a workable approach, instead of selecting the paths without considering how to sensitize, attempt to choose a covering path set that is easy to sensitize and pick hard to sensitize paths only as you must to achieve coverage.
- Identify all variables that affect the decision.
- Classify the predicates as dependent or independent.
- Start the path selection with un correlated, independent predicates.
- If coverage has not been achieved using independent uncorrelated predicates, extend the path set using correlated predicates.
- If coverage has not been achieved extend the cases to those that involve dependent predicates.
- Last, use correlated, dependent predicates.

PATHINSTRUMENTATION:

Σ Path Instrumentation:

- Path instrumentation is what we have to do to confirm that the outcome was achieved by the intended path.
- **Co-incident Correctness:** The coincidental correctness stands for achieving the desired outcome for

wrong
reason.

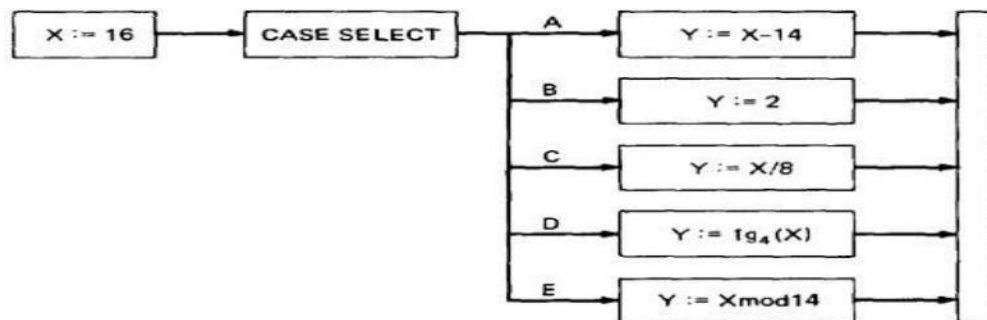

Figure: Coincidental Correctness

Σ The above figure is an example of a routine that, for the (unfortunately) chosen input value ($X = 16$), yields the same outcome ($Y = 2$) no matter which case we select. Therefore, the tests chosen this way will not tell us whether we have achieved coverage. For example, the five cases could be totally jumbled and still the outcome would be the same. **Path Instrumentation** is what we have to do to confirm that the outcome was achieved by the intended path.

- The types of instrumentation methods include:

1. Interpretive Trace Program:

- ← An interpretive trace program is one that executes every statement in order and records the intermediate values of all calculations, the statement labels traversed etc.
- ← If we run the tested routine under a trace, then we have all the information we need to confirm the outcome and, furthermore, to confirm that it was achieved by the intended path.
- ← The trouble with traces is that they give us far more information than we need. In fact, the typical trace program provides so much information that confirming the path from its massive output dump is more work than simulating the computer by hand to confirm the path.

2. Traversal Marker or Link Marker:

- ← A simple and effective form of instrumentation is called a traversal marker or link marker.
- ← Name every link by a lower case letter.
- ← Instrument the links so that the link's name is recorded when the link is executed.
- ← The succession of letters produced in going from the routine's entry to its exit should, if there are no bugs, exactly correspond to the path name.

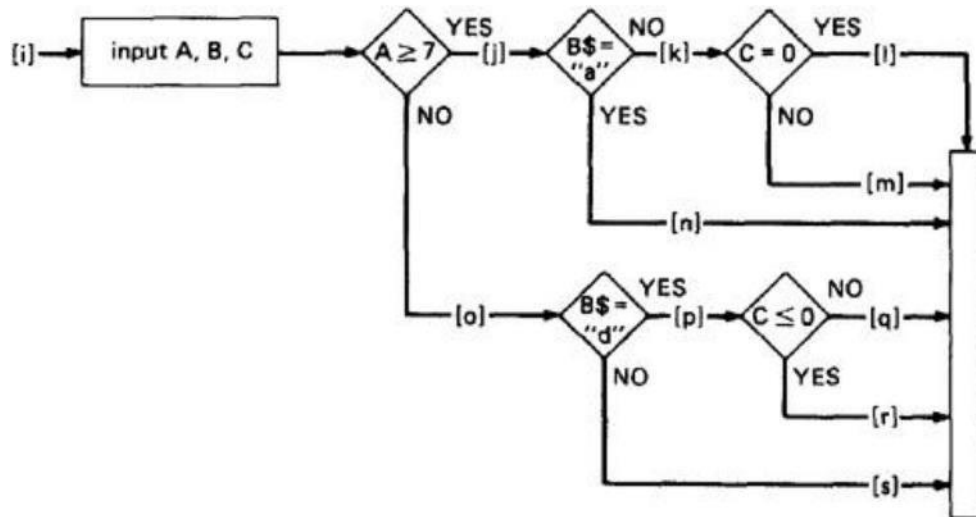

Figure: Single Link Marker Instrumentation

Why Single Link Markers aren't enough: Unfortunately, a single link marker may not do the trick because links can be chewed by open bugs.

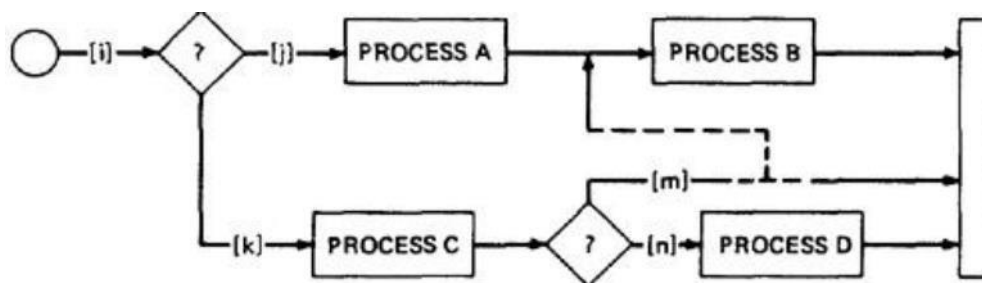

Figure: Why Single Link Markers aren't enough.

We intended to traverse the ikm path, but because of a rampaging GOTO in the middle of the m link, we go to process B. If coincidental correctness is against us, the outcomes will be the same and we won't know about the bug.

3. Two Link Marker Method:

- ← The solution to the problem of single link marker method is to implement two markers per link: one at the beginning of each link and one at the end.
- ← The two link markers now specify the path name and confirm both the beginning and end of the link.

Figure: Double Link Marker Instrumentation.

4. **Link Counter:** A less disruptive (and less informative) instrumentation method is based on counters. Instead of a unique link name to be pushed into a string when the link is traversed, we simply increment a link counter. We now confirm that the path length is as expected. The same problem that led us to double link markers also leads us to double link counters.

UNIT 1 - 2 MARKS QUESTIONS WITH ANSWERS

1) What is testing? What is the purpose of testing?

A) TESTING:

After the programs have been developed they must be tested or debugged to ensure that they have no errors.

There are several methods used to test or debug a program. Methods are nothing but techniques. A set of methods and principles used to perform a particular activity is called methodologies.

□ PURPOSE OF TESTING:

Software testing is an activity that is used to evaluate the capabilities of a system and determine if it is in accordance with the specifications.

The purpose of testing is more than just debugging and detecting bugs. Testing is usually performed for the following purposes:

1. For improving and assuring software quality.
2. For verification and validation.
3. For estimating reliability.

2) What are the goals of testing?

- **GOALS OF TESTING:** Two major goals of testing are:

1. Bug prevention.
2. Bug discovery.

1. Bug Prevention:

It is considered as primary goal for testing. When a bug is detected, appropriate method should be used to remove it.

When a particular bug is prevented, there's no need to perform testing again and again.

"Designing tests" are considered as the best bug preventer. It means that if a test is easy to detect and prevent bugs before coding phase.

2. Bug Discovery:

Bug discovery is considered as the secondary goal for testing. It is performed when the primary goal to prevent the bugs.

3) Compare testing and debugging.

TESTING	DEBUGGING
<ol style="list-style-type: none">1. The goal of testing is to detect errors in a program.2. Testing is initiated with known conditions.3. The output can be expected.4. It is necessary to have planned, designed and scheduled constraints.5. Testing finds the reason for program's failure.6. It is not necessary to have design knowledge while performing testing.7. Testing is performed by a person who does not belong to the company.	<ol style="list-style-type: none">1. The goal of debugging is to detect errors and correct them.2. Debugging is initiated with unknown conditions.3. The output cannot be expected.4. In debugging, it is not necessary to have these constraints.5. Debugging is the programmer's capability.6. It is sufficient to have detailed design knowledge for debugging.7. Debugging should be done by a person who belongs to the company.

4) **Compare Functional testing and structural testing.**

FUNCTIONAL TESTING	STRUCTURAL TESTING
<ol style="list-style-type: none">1. Functional testing is also called as black box testing or closed box testing.2. Functional tests are performed without the knowledge of internal structure of software.3. The test cases take infinite time to detect all errors.4. Functional testing is more effective than glass box testing5. Different methods for performing black box testing are:<ol style="list-style-type: none">a. Expected inputs methodsb. Boundary values methods.c. Illegal values methods.	<ol style="list-style-type: none">1. Structural testing is also called as white box testing or glass box or open box testing.2. Structural tests are performed based on the knowledge of internal structure of the software.3. The test cases take finite time but cannot detect all bugs.4. Structural testing is less effective when compared to functional testing5. Different methods for performing white box testing are:<ol style="list-style-type: none">a. Statement testingb. Decision testingc. Condition testing.

5) **Compare designer and tester.**

DESIGNER	TESTER
<ol style="list-style-type: none">1. Designer is based on the structural specification of the system.2. Designer depends on the implementation details.3. The knowledge of implementation makes the designer to design the software very effectively.4. A software designer is responsible for designing and executing the tests.	<ol style="list-style-type: none">1. Tester is based on the functional specifications of the system.2. Tester is independent of the implementation.3. Due to lack of implementation details, the developed software is ineffectively.4. A tester is responsible for designing and executing tests.

6) **Compare small programs and large programs.**

SMALL	LARGE
<ol style="list-style-type: none">1. Small programs have only few lines of code.2. They consist of few components.3. Small programs do not require any technique for testing.4. Small programs are more efficient.5. Small program are written by a single programmer.6. The quality of small program is high compared to that of a high compared to that of a large component.	<ol style="list-style-type: none">1. Large programs have number of lines of code.2. They consist of large components.3. They require different types of techniques for testing.4. Large programs are less efficient.5. Large programs are written by different programmers.6. The quality of large program is low when compared to small program.

7) **What is the metric that shows the importance of bug?**

- **IMPORTANCE OF BUGS:**

Bugs are the errors that cause the program to generate an incorrect output.

The importance of a bug depends on frequency, correction cost, installation cost and consequences.

1. **FREQUENCY:** The no. of times the bug occurred is called frequency of the bug.
2. **CORRECTION COST:** Once the bug has detected, it need to be corrected.
Correction cost is nothing but the cost that occurs during the error process. This cost depends upon the following two factors: a. Bugdetection cost b. Bug correction cost.
3. **INSTALLATION COST:** It depends upon the no. of installations. The installation cost is low for a single user program.
4. **CONSEQUENCES:** We must measure the result or effect of the bug.
Importance of the bug (\$) = (correction cost + installation cost + consequential cost)

8) **What are the 3 quality aspects of software quality?**

Testing is usually performed for the following purposes:

1. For improving and assuring software quality.
2. For verification and validation.
3. For estimating reliability.

1. **SOFTWARE QUALITY ASSURANCE [SQA]:**

Quality is used to determine if the software meets all the requirements that were specified during design phase.

Software Quality Assurance is used to monitor the Software engineering processes and methods for ensuring its quality.

2. **VERIFICATION AND VALIDATION:**

Verification and Validation is done to test the quality of software. Based on the test results, testers make decisions whether the product will work properly or not.

The specifications and test results of different products are compared to know which product has better quality.

The quality is not tested directly but the related aspects of the quality are tested to make software noticeable.

Software quality has 3 aspects such as Functionality, Engineering, and Adaptability. These aspects are used to measure the scope of software quality.

- i. **Functionality:** It is an exterior quality factor. It is determined by considering Correctness, Reliability, Usability and Integrity of the product.
- ii. **Engineering:** It is an interior quality factor. It is determined by considering efficiency, Testability, Documentation and Structure of a product.
- iii. **Adaptability:** It is a future quality factor. It is determined by considering Flexibility, Reusability and maintainability of a product.

9) **What is a control flow graph? What are the 3 important elements of control flow graph?**

□ **CONTROL FLOWGRAPHS:**

A control flow graph is a form of flowchart which does not deal with the internal structure of the process; rather it deals with the data flow and the control flow between the processes.

Every control flow graph has some important elements:

1. Process blocks.
2. Decisions and case statements.
3. Junctions.

10) **Define a Process block.**

A process block is a sequence of program statements. In this process block, if any one statement is executed, then all other statements of this block will be executed.

A process block can contain one statement or hundred statements.
 Once a process block is initiated, every statement within it will be executed. —————→ DO
 Similarly there is no point of GOTO statement in these blocks. A
 It contains one ENTRY and one EXIT.

11) **What are decision statements and case statement?**

Decision is a program point at which the control flow can split.
 The flow gets diverted in one of the many options available. EXAMPLE: IF then ELSE
 Most decisions are two-way or binary. Some may be three way branches in control flow.
 Generally two-way branches are easier than three way branches. Case stmt is a multi-way branch or decisions. According to the case variable value, the particular block will be executed.
 According to the test design, there are no fundamental differences between decisions and case statements.

Fig (1): TWO WAY DECISIONS.

Fig (2): CASE STATEMENTS

12) **What are the differences between Control flow graphs and flowcharts?**

CONTROL FLOWGRAPHS	FLOW CHARTS
1. In control flow graphs we don't show the details of the process in the process in the block.	1. In flow chart, each and every statement of the process will be shown separately.
2. Here total statements are shown as single process. There is no need to know how many statements are in it.	2. Every statement is shown. If the process contains 100 steps / statements, they must be shown in 100 process blocks.
3. Flow graph representation is easy to understand.	3. Flowchart creates confusion in control flow.
4. Now-a-days control flow graphs are used more in developments.	4. Now-a-days flow charts are not used in many purposes.

13) **Define Path.**

A series of statements initiating from an entry and terminating at an exit, thereby passing through the junctions and decisions is known as path. Every path consists of a set of processes known as links.
 Example:

There are 2 different paths from an entry (A) to an exit (B). They are ACDEB and ACDB respectively.

Though both paths are simple, the most obvious among the 2 is ACBD because it is shortest path between an entry and an exit.

14) Define Node and Link.

Nodes are the graphical representation of real world objects. Nodes are mainly denoted by small circles.

A node which has more than one input link is known as Junction. And a node which has more than one output link is known as Decision.

Nodes can be labeled by an alphabets (or) numbers.

Example:

In the above fig, A, B, C, D, E, F are nodes. D is the decision which has 2 output links and F is a junction which has 2 input links.

□ **LINKS:**

A link is mediator for any two nodes. Link can be denoted by an “arrow” can be represented by lower case letters.

15) What is a predicate and explain about a predicate interpretation.

□ **PREDICATES:**

Predicate is a function which is logically executed during the decision processing. The result of this function decides the direction of flow.

□ **PREDICATE INTERPRETATION:**

Consider an example, where the predicate is sum of A & C greater than zero, which is symbolically represented as “ $A+C>0$ ”.

Now let the value of “C” be given using another predicate “ $C:=B+5$ ”

The substitution of “C” value in the first predicate gives you another predicate “ $A+B+5>0$ ”. This process is known as predicate interpretation.

Predicate interpretation refers to the process of expressing the predicate in terms of other predicates.

UNIT-I

PART-A QUESTIONS(2 Marks)

- 1) What is testing? What is the purpose of testing? (Nov-2016)
- 2) What are the goals of testing? (Nov-2017 , June-2016,2017)
- 3) Compare testing and debugging?
- 4) Compare Functional testing and structural testing?
- 5) Write the difference between designer and tester? (Nov-2018)
- 6) Write the difference between small vs large programs?
- 7) What is the metric that shows the importance of bug?
- 8) What are the 3 quality aspects of software quality?
- 9) What is a control flow graph? What are the 3 important elements of control flow graph? (Nov-2018 , June-2017)
- 10) Define a Process block? (Nov-2018 , June-2017)
- 11) What are decision statements and case statement?
- 12) What are the differences between Control flow graphs and flowcharts?
- 13) Define Path? (Nov-2016,2017)
- 14) Define Node and Link? (Nov-2018 , June-2017)
- 15) What is a predicate and explain about a predicate interpretation?

PART-B QUESTIONS(10 Marks)

- 1) What are the applications of Path Testing?
- 2) What are the factors that determine the importance of a Bug? What are the Consequences of Bugs Explain? (Nov-2017)
- 3) What is Flow Graph? Explain the Path testing with respective Path Predicates with Example? (Nov-2017 , June-2018)
- 4) Define Testing Blindness? Explain the three types of Testing Blindness?
- 5) State and explain various dichotomies in software testing?
- 6) What is Flow Graph? Explain the Path testing with respective Path Predicates & Achievable Path with Example? (Nov-2018 , June-2017,2018)
