#### **UNIT IV**

Logic Based Testing: Overview, Decision Tables, Path Expressions, KV Charts, Specifications.

### **LOGIC BASED TESTING-OVERVIEW:**

#### INTRODUCTION:

- The functional requirements of many programs can be specified by decision tables, which provide a useful basis for program and test design.
- Consistency and completeness can be analyzed by using boolean algebra, which can also be used as a basis for test design. Boolean algebra is trivialized by using **Karnaugh-Veitch charts**.
- "Logic" is one of the most often used words in programmers' vocabularies but one of their least used techniques.
- Boolean algebra is to logic as arithmetic is tomathematics. Without it, the tester or programmer is cut
  off from many test and design techniques and tools that incorporate those techniques.
- Logic has been, for several decades, the primary tool of hardware logic designers.
- Many test methods developed for hardware logic can be adapted to software logic testing. Because hardware testing automation is 10 to 15 years ahead of software testing automation, hardware testing methods and its associated theory is a fertile ground for software testing methods.
- As programming and test techniques have improved, the bugs have shifted closer to the process front end, to requirements and their specifications. These bugs range from 8% to 30% of the total and because they're first-in and last-out, they're the costliest of all.
- The trouble with specifications is that they're hard to express.
- o Boolean algebra (also known as the sentential calculus) is the most basic of all logic systems.
- o Higher-order logic systems are needed and used for formal specifications.
- Much of logical analysis can be and is embedded in tools. But these tools incorporate methods to simplify, transform, and check specifications, and the methods are to a large extent based on boolean algebra.

## O KNOWLEDGE BASED SYSTEM:

- The knowledge-based system (also expert system or "artificial intelligence" system has become the programming construct of choice for many applications that were once considered very difficult.
- Knowledge-based systems incorporate knowledge from a knowledge domain such as medicine, law, or civil engineering into a database. The data can then be queried and interacted with to provide solutions to problems in that domain.
- One implementation of knowledge-based systems is to incorporate the expert's knowledge into a set of rules. The user can then provide data and ask questions based on that data.
- The user's data is processed through the rule base to yield conclusions (tentative or definite) and requests for more data. The processing is done by a program called the **inference engine**.
- Understanding knowledge-based systems and their validation problems requires an understanding of formallogic.
- Decision tables are extensively used in business data processing; Decision-table preprocessors as extensions to COBOL are in common use; boolean algebra is embedded in the implementation of these processors.
- Althoughprogrammedtoolsarenicetohave, mostofthebenefitsof booleanalgebracanbereapedby wholly manual means if you have the right conceptual tool: the Karnaugh-Veitch diagram is that conceptual tool.

#### **DECISION TABLES:**

- The below Figure is a limited entry decision table. It consists of four areas called the condition stub, the condition entry, the action stub, and the action entry.
- Each column of the table is a rule that specifies the conditions under which the actions named in the action stub will take place.
- The condition stub is a list of names of conditions.

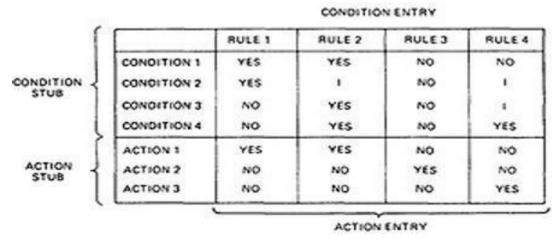

Figure: Examples of Decision Table.

A more general decision table can be as below:

#### Printer troubleshooter Rules Y N N Printer does not print N N Conditions A red light is flashing N N Y N Y N Y N Y Printer is unrecognised N Check the power cable X X X Check the printer-computer cable Actions Ensure printer software is installed X X X X XX X X Check/replace ink Check for paper jam

Figure: Another Example of Decision Table.

- A rule specifies whether a condition should or should not be met for the rule to be satisfied. "YES" means that the condition must be met, "NO" means that the condition must not be met, and "I" means that the condition plays no part in the rule, or it is immaterial to that rule.
- The action stub names the actions the routine will take or initiate if the rule is satisfied. If the action entry is "YES", the action will take place; if "NO", the action will not take place.
- The table in Figure 6.1 can be translated as follows:
  Action 1 will take place if conditions 1 and 2 are met and if conditions 3 and 4 are not met (rule 1) or if conditions 1, 3, and 4 are met (rule 2).
- "Condition" is another word for predicate.
- Decision-table uses "condition" and "satisfied" or "met". Let us use "predicate" and TRUE / FALSE.
- Now the above translations become:

- 1. Action 1 will be taken if predicates 1 and 2 are true and if predicates 3 and 4 are false (rule 1), or if predicates 1, 3, and 4 are true (rule 2).
- 2. Action 2 will be taken if the predicates are all false, (rule 3).
- 3. Action 3 will take place if predicate 1 is false and predicate 4 is true (rule 4).
- In addition to the statedrules, we also need a Default Rule that specifies the default action to be taken when all other rules fail. The default rules for Table in Figure 6.1 is shown in Figure.

|             | Rule 5 | Rule 6 | - Rule 7 | Rule 8 |  |
|-------------|--------|--------|----------|--------|--|
| CONDITION 1 | 1      | NO     | YES      | YES    |  |
| CONDITION 2 | 1      | YES    | 1        | NO     |  |
| CONDITION 3 | YES    | 1      | NO       | NO     |  |
| CONDITION 4 | NO     | NO     | YES      | 1.1    |  |
| DEFAULT     | YES    | YES    | YES      | YES    |  |

Figure: The default rules of Table in Figure 6.1

### Decision-table processors:

- o Decision tables can be automatically translated into code and, as such, area higher-order language
- o If the rule is satisfied, the corresponding action takes place
- Otherwise, rule 2 istried. This process continues until either a satisfied rule results in an action or no rule is satisfied and the default action is taken
- o Decision tables have become a useful tool in the programmer's kit, in business data processing.

#### Decision-tables as basis for test case design:

- 0. The specification is given as a decision table or can be easily converted into one.
- 1. The order in which the predicates are evaluated does not affect interpretation of the rules or the resulting action i.e., an arbitrary permutation of the predicate order will not, or should not, affect which action takes place.
- 2. The order inwhich therules are evaluated does not affect the resulting action i.e., an arbitrary permutation of rules will not, or should not, affect which action takes place.
- 3. Once a rule is satisfied and an action selected, no other rule need be examined.
- 4. If several actions can result from satisfying a rule, the order in which the actions are executed doesn't matter

#### • Decision-tables and structure:

- o Decision tables can also be used to examine a program's structure.
- Figure 6.4 shows a program segment that consists of a decision tree.
- These decisions, in various combinations, can lead to actions 1, 2, or 3.

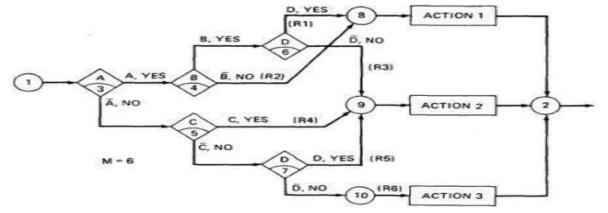

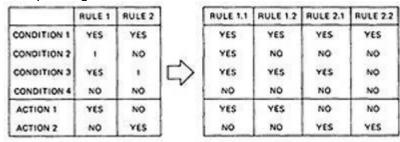

Figure: A Sample Program

- o If the decision appears on a path, put in a YES or NO as appropriate. If the decision does not appear on the path, put in an I, Rule 1 does not contain decision C, therefore its entries are: YES, YES, I, YES.
- The corresponding decision table is shown in Table 6.1

|                                                 | RULE 1 | RULE 2 | RULE 3 | RULE 4 | RULE 5 | RULE 6 |
|-------------------------------------------------|--------|--------|--------|--------|--------|--------|
| CONDITION A CONDITION B CONDITION C CONDITION D | YES    | YES    | YES    | NO     | NO     | NO     |
|                                                 | YES    | NO     | YES    | I      | I      | I      |
|                                                 | I      | I      | I      | YES    | NO     | NO     |
|                                                 | YES    | I      | NO     | I      | YES    | NO     |
| ACTION 1                                        | YES    | YES    | NO     | NO     | NO     | NO     |
| ACTION 2                                        | NO     | NO     | YES    | YES    | YES    | NO     |
| ACTION 3                                        | NO     | NO     | NO     | NO     | NO     | YES    |

Table: Decision Table corresponding to Figure 6.4

As an example, expanding the immaterial cases results as below:

o Similarly, If we expand the immaterial cases for the above Table, it results in Table as below:

|                                                 | R1 | RULE 2 | R3 | RULE 4 | R5 | R6 |
|-------------------------------------------------|----|--------|----|--------|----|----|
| CONDITION A CONDITION B CONDITION C CONDITION D | YY | YYYY   | YY | NNNN   | NN | NN |
|                                                 | YY | NNNN   | YY | YYNN   | NY | YN |
|                                                 | YN | NNYY   | YN | YYYY   | NN | NN |
|                                                 | YY | YNNY   | NN | NYYN   | YY | NN |

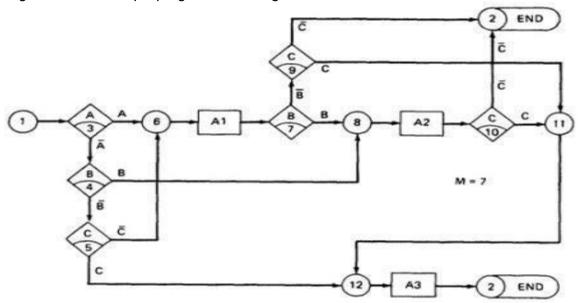

**Table: Expansion of Table** 

- o Sixteen cases are represented in Table 6.1, and no case appears twice.
- o Consequently, the flow graph appears to be complete and consistent.
- Asafirstcheck, beforeyoulookforallsixteencombinations, countthenumber of Y's and N's in each row. They should be equal. We can find the bug that way.

### • Another example - a trouble some program:

- Consider the following specification whose putative flow graph:
  - 1. If condition A is met, do process A1 no matterwhat other actions are taken or what other conditions are met.
  - 2. If condition B is met, do process A2 no matter what other actions are taken or what other conditions are met.
  - 3. If condition C is met, do process A3 no matter what other actions are taken or what other conditions are met.
  - 4. If none of the conditions is met, then do processes A1, A2, and A3.

- 5. When more than one process is done, process A1 must be done first, then A2, and then A3. The only permissible cases are: (A1), (A2), (A3), (A1,A3), (A2,A3) and (A1,A2,A3).
- Figure shows a sample program with a bug.

**Figure: A Troublesome Program** 

The programmer tried to force all three processes to be executed for the Band C predicates would be done again, thereby by passing processes A2 and A3.

RULES

o Table 6.3 shows the conversion of this flow graph into a decision table after expansion.

|             | HOLES |     |     |     |     |     |     |     |
|-------------|-------|-----|-----|-----|-----|-----|-----|-----|
|             | ĀBC   | ÄBC | ÃBC | ÃBČ | ABČ | ABC | ABC | ABC |
| CONDITION A | NO    | NO  | NO  | NO  | YES | YES | YES | YES |
| CONDITION B | NO    | NO  | YES | YES | YES | YES | NO  | NO  |
| CONDITION C | NO    | YES | YES | NO  | NO  | YES | YES | NO  |
| ACTION 1    | YES   | NO  | NO  | NO  | YES | YES | YES | YES |
| ACTION 2    | YES   | NO  | YES | YES | YES | YES | NO  | NO  |
| ACTION 3    | YES   | YES | YES | NO  | NO  | YES | YES | NO  |

**Table: Decision Table** 

#### **PATH EXPRESSIONS:**

#### General:

- Logic-based testing is structural testing when it's applied to structure (e.g., control flowgraph of an implementation); it's functional testing when it's applied to a specification.
- In logic-based testing we focus on the truth values of control flow predicates.
- o A predicate is implemented as a process whose outcome is a truth-functional value.
- For our purpose, logic-based testing is restricted to binary predicates.
- Westart by generating path expressions by path tracing as in Unit V, but this time, our purpose is to convert the path expressions into boolean algebra, using the predicates' truth values (e.g., A and Ā) as weights.

### Boolean algebra:

- Steps:
  - 1. Label each decision with an uppercase letter that represents the truth value of the predicate. The YES or TRUEbranchislabeled with aletter (say A) and the NO or FALSE branch with the same letter overscored (say A).
  - 2. The truth value of a path is the product of the individual labels. Concatenation or products mean "AND". For example, the straight-through path of Figure 6.5, which goes via nodes 3, 6, 7, 8, 10, 11, 12, and 2, has atruth value of ABC. The path via nodes 3, 6, 7, 9 and 2 has a value of ABC.
  - 3. If two or more pathsmergeat anode, the fact is expressed by use of a plussign (+) which means "OR".

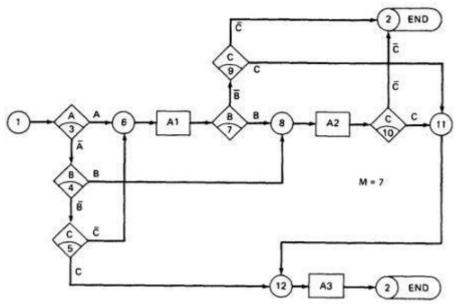

Figure: A Troublesome Program

Using this convention, the truth-functional values for several of the nodes can be expressed in terms of segments from previous nodes. Use the node name to identify the point.

$$N6 = A + \overline{A}\overline{B}\overline{C}$$

$$N8 = (N6)B + \overline{A}B = AB + \overline{A}\overline{B}\overline{C}B + \overline{A}B$$

$$N11 = (N8)C + (N6)\overline{B}C$$

$$N12 = N11 + \overline{A}\overline{B}C$$

$$N2 = N12 + (N8)\overline{C} + (N6)\overline{B}\overline{C}$$

- There are only two numbers in boolean algebra: zero (0) and one (1). One means "always true" and zero means "alwaysfalse".
- Rules of booleanalgebra:
  - Booleanalgebrahasthreeoperators: X(AND), +(OR) and Ā (NOT)
  - X: meaning AND. Also called multiplication. A statement such as AB (A X B) means "A and B are both true". This symbol is usually left out as in ordinary algebra.
  - +: meaning OR. "A + B" means "either A is true or B is true or both".
  - The entire expression under the bar is negated.
     The entire expression under the bar is negated.
  - The following are the laws of boolean algebra:

```
If something is true, saying it
                                     twice doesn't make it truer, ditto
                                     for falsehoods.
2. A + 1
                                     If something is always true, then
                                     "either A or true or both" must
                                     also be universally true.
3. A + 0
4. A + B
5. A + A
                  = B + A
                                     Commutative law.
                                     If either A is true or not-A is true.
                                     then the statement is always true.
6. AA
7. A × 1
8. A × 0
                  = 0
9. AB
                  = BA
IO. AA
                                     A statement can't be simulta-
                  = 0
                                     neously true and false.
"You ain't not going" means you
1. A
                                     are. How about, "I ain't not never
                                     going to get this nohow."?
12. 0
3. 1
4. A + B
                                     Called "De Morgan's theorem or
                                     law."
5. AB
                  = \overline{A} + \overline{B}
6. A(B + C)
                  = AB + AC
                                     Distributive law.
7. (AB)C
                  = A(BC)
                                     Multiplication is associative.
8. (A + B) + 9. A + \overline{A}B
              C = A + (B + C)
                                     So is addition.
                  = A + B
                                     Absorptive law.
0. A + AB
                  = A
```

- o In all of the above, aletter can represent a single sentence or an entire boolean algebra expression.
- o Individual letters in a boolean algebra expression are called Literals (e.g. A,B)
- o The product of several literals is called a product term (e.g., ABC, DE).
- An arbitrary boolean expression that has been multiplied out so that it consists of the sum of products (e.g., ABC + DEF + GH) is said to be in sum-of-products form.
- The resultof simplifications (using the rules above) is again in the sum of product form and each product term in such a simplified version is called a prime implicant. For example, ABC + AB + DEF reduces by rule 20 to AB + DEF; that is, AB and DEF are prime implicants.
- The path expressions of Figure 6.5 can now be simplified by applying the rules.
- The following are the laws of boolean algebra:

$$N6 = A + \overline{A} \overline{B} \overline{C}$$

$$= A + \overline{B} \overline{C}$$

$$= A + \overline{B} \overline{C}$$

$$= (N6)B + \overline{A}B$$

$$= (A + \overline{B} \overline{C})B + \overline{A}B$$

$$= AB + \overline{B} \overline{C}B + \overline{A}B$$

$$= AB + BBC + \overline{A}B$$

$$= AB + BBC + \overline{A}B$$

$$= AB + OC + \overline{A}B$$

$$= AB + O + \overline{A}B$$

$$= AB + O + \overline{A}B$$

$$= AB +$$

Similarly,

```
N11 = (N8)C + (N6)\overline{B}C
        = BC + (A + \overline{B}\overline{C})\overline{B}C
                                                          : Substitution.
        = BC + A\overline{B}C
                                                          : Rules 16, 9, 10, 8, 3.
        = C(B + \overline{B}A)
                                                          : Rules 9, 16.
       = C(B + A)
                                                          : Rule 19.
        = AC + BC
                                                          : Rules 16, 9, 9, 4.
N12 = N11 + \overline{ABC}
        = AC + BC + \overline{A}\overline{B}C
        = C(B + \overline{A}\overline{B}) + AC
        = C(\overline{A} + B) + AC
        = C\overline{A} + AC + BC
        = C + BC
        = C
N2 = N12 + (N8)\overline{C} + (N6)\overline{B}\overline{C}
       = C + B\overline{C} + (A + \overline{B}\overline{C})\overline{B}\overline{C}= C + B\overline{C} + \overline{B}\overline{C}
       = C + \overline{C}(B + \overline{B})
        = C + C
```

o The deviation from the specification is now clear. The functions should have been:

```
N6 = A + \overline{A}\overline{B}\overline{C} = A + \overline{B}\overline{C} : correct.

N8 = B + \overline{A}\overline{B}\overline{C} = B + \overline{A}\overline{C} : wrong, was just B.

N12 = C + \overline{A}\overline{B}\overline{C} = C + \overline{A}\overline{B} : wrong, was just C.
```

 Loops complicate things because we may have to solve a boolean equation to determine what predicate-value combinations lead to where.

#### **KV CHARTS:**

#### Introduction:

- o If you had to deal with expressions in four, five, or six variables, you could get bogged down in the algebra and make as many errors in designing test cases as there are bugs in the routine you're testing.
- o Karnaugh-Veitch chart reduces boolean algebraic manipulations to graphical trivia.
- Beyond six variables these diagrams get cumbersome and may not be effective.

#### Single Variable:

Figure shows all the boolean functions of a single variable and their equivalent representation as a KV chart.

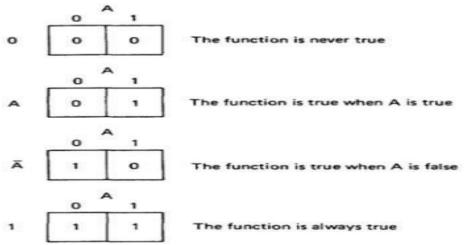

Figure: KV Charts for Functions of a Single Variable.

- o The charts show all possible truth values that the variable A can have.
- o A"1" means the variable's value is "1" or TRUE. A"0" means that the variable svalue is 0 or FALSE.
- The entry in the box (0 or 1) specifies whether the function that the chart represents is true or false for that value of the variable.
- Weusually do not explicitly put in 0 entries but specify only the conditions under which the function is true.

### Two variables:

Figure shows eight of the sixteen possible functions of two variables.

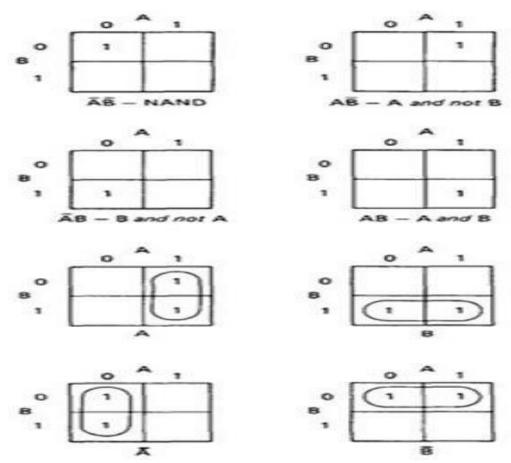

Figure: KV Charts for Functions of Two Variables.

- o Each box corresponds to the combination of values of the variables for the row and column of that box.
- o A pair may be adjacent either horizontally or vertically but not diagonally.
- o Anyvariablethatchangesin either thehorizontalorverticaldirectiondoesnot appear in the expression.
- o Inthe fifth chart, the B variable changes from 0 to 1 going down the column, and because the A variable's value for the column is 1, the chart is equivalent to a simple A.

Figure shows the remaining eight functions of two variables.

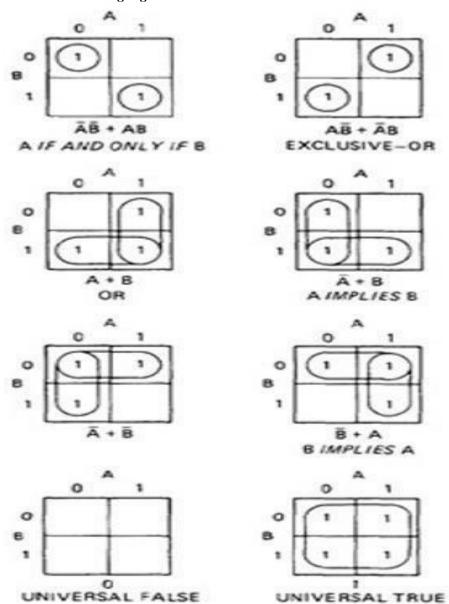

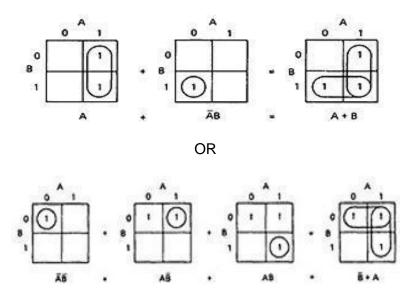

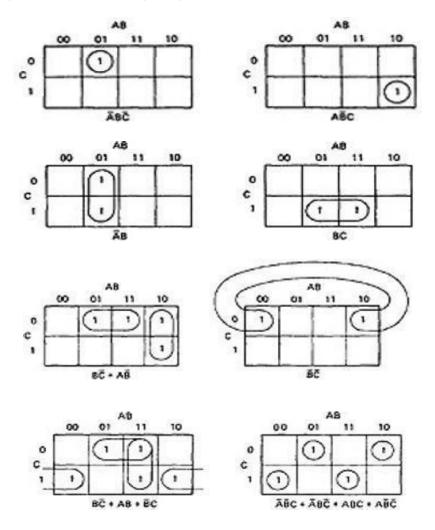

Figure: More Functions of Two Variables.

- o The first chart has two 1's in it, but because they are not adjacent, each must be taken separately.
- They are written using a plus sign.
- It is clear now why there are sixteen functions of two variables.
- Each box in the KV chart corresponds to a combination of the variables' values.
- That combination might or might not be in the function (i.e., the box corresponding to that combination might have a 1 or 0 entry).
- Since n variables lead to 2<sup>n</sup> combinations of 0 and 1 for the variables, and each such combination (box) can be filled or not filled, leading to 2<sup>2n</sup> ways of doing this.
- Consequently for one variable there are  $2^{21} = 4$  functions, 16 functions of 2 variables, 256 functions of 3 variables, 16,384 functions of 4 variables, and so on.
- o Giventwo charts over the same variables, arranged the same way, their product is the term by term product, their sum is the term by term sum, and the negation of a chart is gotten by reversing all the 0 and 1 entries in the chart.

### • Three variables:

- o KV charts for three variables are shown below.
- As before, each box represents an elementary term of three variables with a bar appearing or not appearing according to whether the row-column heading for that box is 0 or 1.
- A three-variable chart can have groupings of 1, 2, 4, and 8 boxes.
- A few examples will illustrate the principles:

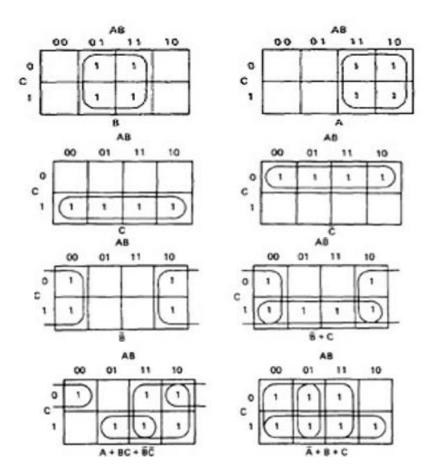

Figure: KV Charts for Functions of Three Variables.

### **SPECIFICATIONS:**

The procedure for specification validation is straight forward.

- 1. Rewrite the specification using consistent terminology.
- 2. Identify the predicates on which the cases are based. Name them with suitable letters such as A, B, C.
- 3. Rewrite the specification in English that uses only the logical connectives AND, OR and NOT, however stilted it might seem.
- 4. Convert the rewritten specification into an equivalent set of Boolean expressions.
- 5. Identify the default action and cases, if they are specified.
- 6. Enter the Boolean expressions in a KV Chart and check for consistency. If the specification are consistent, there will be no overlaps, except for cases that result in multiple actions.
- 7. Enter the default cases and check for consistency.
- 8. If all boxes are covered, the specification is complete.
- 9. If the specification is incomplete or inconsistent, translate the corresponding boxes of the KV Chart back into English and get a clarification, explanation or revision.
- 10. If the default cases were not specified explicitly, translate the default cases back into English and get a confirmation.

## **UNIT 4 - 2 MARKS QUESTIONS WITH ANSWERS**

## 1) Define the term path expressions?

It is defined as an expression which represents set of all the possible paths between any entry and an exit nodes. Path expressions play an important role during debugging. It surveys the structure of any flow graph which includes number of paths, time required to process a path, any inconsistency among data flow.

### 2) Define flow graph. Write any three uses of flow graphs?

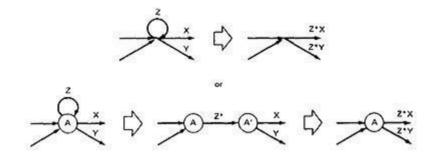

A flow graph is a graph consisting of nodes as well as directed links. Each link a node is represented by different lables (1,2,3...), (a,b,c,...).

Uses of flow graph:

- To represent flow of control in a routine.
- Used in software development, testing, debugging tools.
- Used in designing and analysing circuits.

## 3) what are the loop removal operations?

• There are two ways of looking at the loop-removal operation:

- In the first way, we remove the self-loop and then multiply all outgoing links by Z\*.
- In the second way, wesplit the node into two equivalent nodes, call them Aand A' and put in a link between them whose path expression is Z\*. Then we remove node A' using steps 4 and 5 to yield outgoing links whose path expressions are Z\*X and Z\*Y.

### 4)HOW MANY PATHS IN A FLOWGRAPH?

- Determining the actual number of different paths is an inherently difficult problem because there could be unachievable paths resulting from correlated and dependent predicates.
- Ifweknowbothofthesenumbers (maximumand minimumnumber ofpossiblepaths) wehavea goodidea ofhow complete our testing is.
- · Asking for "the average number of paths" is meaningless.

## 5) List the three arithmetic rules used to calculate mean processing time?

**Parallel rule:** Is the arithmetic mean of all execution time over all parallel links in a flow graph.

**Series rule:** It is the sum of two execution times.

**Loop rule:** Is the combination of parallel and series rule.

## 6) What are the applications of decision tables?

- Employed in business data processing.
- Used for genenrating a high level code.
- Employed in business analysis, programming, testing, design of hardware.

# 7) what is a decision table?

Desicion tables represents higher level language as they can be translated into program code automatically. The translator of decision table is responsible for checking whether the source decision table is reliable and complete. It also checks whether any default rules are required and specifies them if needed.

### **UNIT-IV**

## PART-A QUESTIONS(2 Marks)

- 1) Define the term path expressions?
- 2) Define flow graph. Write any three uses of flow graphs? (Nov-2016,2018, June-2018)
- 3) What are the loop removal operations? (June-2016)
- 4) How many paths in a flow graph? (Nov-2018, June-2018)
- 5) List the three arithmetic rules used to calculate mean processing time?
- 6) What are the applications of decision tables? (Nov-2016, June-2017)
- 7) What is a decision table?

## PART-B OUESTIONS(10 Marks)

- 1) Discuss how the decision tables can be Basis for test case design?
- 2) Explain about KV Charts for one, two & three Variables and its Specifications? (Nov-2017, June-2018)
- 3) Explain Regular expressions and flow anomaly detection? (Nov-2018, June-2018)
- 4) What is the looping probability of a path expression? Explain with an example. (Nov-2018, June-2018)
